

Bagging and Boosting: Resampling for Classifier Design

Sargur Srihari

srihari@cedar.buffalo.edu

Bagging

- *Arcing*— adaptive re-weighting and combining— refers to reusing or selecting data to improve classification
- Includes both *bagging* and *boosting*
- Simplest method is *bagging*
- Name derived from *bootstrap aggregation*
- Uses multiple versions of training set

Bagging Method

- Drawing $n' < n$ samples from D with replacement
- Each bootstrap set is used to train a different component classifier
- Final classification decision based on vote of each component classifier
- Component classifiers are all of the same form
 - all HMMs, all neural networks, all decision trees
 - Different parameter values due to different training sets

Bagging Overcomes Classifier Instability

- Unstable if small changes in training data lead to significantly different classifiers or large changes in accuracy
- Decision Tree algorithms can be unstable
 - Slight change in the position of a training point can lead to a radically different tree
- Bagging improves recognition for unstable classifiers by smoothing over discontinuities

Boosting

- Powerful technique for combining multiple “base” classifiers to form a committee whose performance can be significantly better than any of the base classifiers
- *AdaBoost* (adaptive boosting) can give good results even if base classifier performance is only slightly better than random
- Hence base classifiers are known as *weak learners*
- Designed for classification, can be used for regression as well

Boosting versus Bagging

- Base classifiers are trained in sequence
- Each base classifier trained using a weighted form of the dataset
 - Weighting coefficient depends on the performance of the previous classifiers
 - Points misclassified by one of the classifiers is given more weight when used to train next classifier
- Decisions are combined using a weighted majority weighting scheme

Boosting with 2D two-category problem

- Component classifiers trained using LMS
- Training sets selected by basic boosting procedure

Classification Task

Voting of Components

Creating Classifier Sequence

- Randomly select $n_1 < n$ patterns form full training set D
- Train the first classifier C_1 with D_1
- C_1 only need be a weak learner, accuracy only slightly better than chance
- Seek to find second learning set D_2 that is most “informative”

Creating Second Training Set

- Informative set will be taken from the remaining samples from D
 - such that half are classified correctly and half are classified incorrectly by C_1
- Can be done by flipping a coin
 - if heads choosing a misclassified sample
 - if tails a correctly classified sample
- Now train a second component classifier C_2 with D_2

Creating third data set

- Seek data set D_3 which are not well classified by voting by C_1 and C_2
- Select samples remaining in D and include them only if C_1 and C_2 disagree
- Use of the ensemble of three classifiers:
 - If C_1 and C_2 agree then use that label
 - If they disagree use the label given by C_3
- Choice of n_1
 - Roughly equal numbers for the three classifiers

Boosting

- Boosting can be recursively applied to the classifiers themselves creating more classifiers
 - With 9 or 27 classifiers very low training error can be achieved
- Continue adding weak learners until some desired low error has been achieved
- Focuses on difficult patterns by giving them more weight

Adaptive Boosting

- Continue adding weak learners until some desired low error has been achieved
- Each training pattern receives a weight that determines its probability of being selected
 - Lower weight for those correctly classified
 - Initially uniform weights across training set
 - On iteration k draw training set according to weights and train classifier C_k
 - Repeat to get C_{k+1}
 - Until sufficient number k_{max} of classifiers are generated

Algorithm AdaBoost

```
1 begin initialize  $\mathcal{D} = \{\mathbf{x}^1, y_1, \dots, \mathbf{x}^n, y_n\}, k_{max}, W_1(i) = 1/n, i = 1, \dots, n$ 
2    $k \leftarrow 0$ 
3   do  $k \leftarrow k + 1$ 
4     train weak learner  $C_k$  using  $\mathcal{D}$  sampled according to  $W_k(i)$ 
5      $E_k \leftarrow$  training error of  $C_k$  measured on  $\mathcal{D}$  using  $W_k(i)$ 
6      $\alpha_k \leftarrow \frac{1}{2} \ln[(1 - E_k)/E_k]$ 
7      $W_{k+1}(i) \leftarrow \frac{W_k(i)}{Z_k} \times \begin{cases} e^{-\alpha_k} & \text{if } h_k(\mathbf{x}^i) = y_i \text{ (correctly classified)} \\ e^{\alpha_k} & \text{if } h_k(\mathbf{x}^i) \neq y_i \text{ (incorrectly classified)} \end{cases}$ 
8   until  $k = k_{max}$ 
9   return  $C_k$  and  $\alpha_k$  for  $k = 1$  to  $k_{max}$  (ensemble of classifiers with weights)
10 end
```

Class label

Weights uniform

Error measured w.r.t. distrib W

As E increases α decreases

Class decision of C_k

Normalizing constant to ensure W is a distrib

AdaBoost Ensemble Decision

- Final classification is given by

$$g(x) = \sum_{k=1}^{k_{\max}} \alpha_k h_k(x)$$

- In two class case this is same as $\text{sgn}[g(x)]$

Illustration of AdaBoost

- Weak Learner: Threshold applied to one or other axis
- Ensemble decision boundary is Green
- Current base learner is dashed black line
- Size of circle indicates weight assigned

AdaBoost Error Rates

- Ensemble Error rate keeps decreasing.
- Individual Classifiers perform worse on weighted training sets

Learning with Queries

- Data Set is unlabeled
- There exists a process for labeling that is costly
 - Handwritten numeral classification
- Present a pattern to an oracle (teacher) who will label pattern without error

Learning with Queries

Active learning can result in more accurate classifiers than with i.i.d. sampling

1. Bayes Classifier for Two Gaussians

2. Nearest_neighbor
with 30 samples
and i.i.d. sampling

3. Queries posed for the
extremes of feature space
midway between two points
already selected
