

CSE 555 Introduction to Pattern Recognition  
Final Exam  
Spring, 2006  
(100 points, 2 hours, Closed book/notes)

*Notice: There are 6 questions in this exam. Page 3 contains some useful formulas.*

1. (15pts) Given two vectors  $X$  and  $Y$ , in a  $d$ -dimensional space, determine whether the following distance measure functions  $D(X, Y)$  are metrics and give the reason.

(a)  $D(X, Y) = \frac{X^T Y}{|X||Y|}$

(b)  $D(X, Y) = (X - Y)^T W (X - Y)$ , where  $W$  is a  $d \times d$  matrix

(c) For binary vectors,

$$D(X, Y) = \frac{1}{2} - \frac{S_{11}S_{00} - S_{10}S_{01}}{2\sqrt{(S_{10} + S_{11})(S_{01} + S_{00})(S_{11} + S_{01})(S_{00} + S_{10})}}$$

where  $S_{ij}$  ( $i, j \in \{0, 1\}$ ) is the number of occurrences of matches with  $i$  in the  $X$  and  $j$  in  $Y$  at the corresponding positions.

2. (15pts) The  $k$ -nearest neighbor decision rule is one of the simplest decision rules to implement and has a good performance in practice. Answer the following questions.

(a) Suppose the Bayes error rate for a  $c = 3$  category classification problem is 5%. What are the bounds on the error rate of a nearest-neighbor classifier trained with an “infinitely large” training set?

(b) How should we select the value of  $k$ ?

(c) One of the well-known methods to reduce the complexity of the nearest neighbor classifier is called *editing, pruning or condensing*. (i) Briefly describe this nearest-neighbor editing procedure. (ii) Illustrate the editing procedure with a simple 2-class 2-dimensional data set.

3. (15pts) Linear Discriminant Functions

(a) What is the definition of a “*linear machine*”?

(b) In a multicategory classification problem, how to determine the hyperplane  $H_{ij}$  between the decision regions  $R_i$  and  $R_j$  by using a linear machine?

(c) In Support Vector Machines (SVM), what are the “*support vectors*”?

4. (15pts) Multilayer Neural Networks.

- (a) Draw a  $d$ - $n_H$ - $c$  fully connected three-layer neural network and give the proper notations.
- (b) Suppose the network is to be trained using the following criterion function

$$J = \frac{1}{4} \sum_{k=1}^c (t_k - z_k)^4$$

Derive the learning rule  $\Delta\omega_{kj}$  for the hidden-to-output weights.

5. (25pts) Unsupervised Learning.

- (a) (5pts) Suppose we want to cluster  $n$  samples into  $c$  clusters,
- what is the definition of the “Sum-of-Squared-Error” clustering criterion?
  - what is the interpretation of this criterion?
- (b) (10pts) Consider the application of the  $k$ -means clustering algorithm to the following 2-dimensional data for  $c = 2$  clusters (using Euclidean distance measure).

Start with the two cluster means:  $m_1(0) = (0, 0)$  and  $m_2(0) = (3, 3)$ .

- what are the means and the cluster membership at the next iteration?
  - what are the final cluster means and the cluster membership after convergence of the algorithm?
- (c) (10pts) Cluster the same data above using hierarchical clustering algorithm and construct a corresponding dendrogram using the distance measure  $d_{max}(D_i, D_j)$ . You need to show the distances at each level.

6. (15pts) Algorithm-Independent Machine Learning.

- (a) Summarize briefly the “No Free Lunch” theorem, referring specifically to the use of “off training set” data.
- (b) State how cross-validation is used in the training of a general classifier.
- (c) When creating a three-component classifier system for a  $c$ -category problem through standard boosting, we train the first component classifier  $C_1$  on a subset  $D_1$  of the training data. We then select another subset data  $D_2$  for training the second component classifier  $C_2$ . How do we select this  $D_2$  for training  $C_2$ ? Why this way, and not for instance randomly?

### Important formulas

$$P^* \leq P \leq P^* \left( 2 - \frac{c}{c-1} P^* \right)$$

$$\Delta\omega_{kj} = \eta(t_k - z_k) f'(net_k) y_j$$

$$\Delta\omega_{ji} = \eta \left[ \sum_{k=1}^c \omega_{kj} \delta_k \right] f'(net_j) x_i$$

$$d_{max}(D_i, D_j) = \max_{x \in D_i, x' \in D_j} \|x - x'\|$$
