Sequential Data

Sargur Srihari
srihari@buffalo.edu
Sequential Data Examples

- Often arise through measurement of time series
  - Acoustic features at successive time frames in speech recognition
  - Sequence of characters in an English sentence
  - Parts of speech of successive words
  - Snowfall measurements on successive days
  - Rainfall measurements on successive days
  - Daily values of currency exchange rate
  - Nucleotide base pairs in a strand of DNA
Sound Spectrogram of Speech

- “Bayes Theorem”
- Plot of the intensity of the spectral coefficients versus time index
- Successive observations of speech spectrum highly correlated (Markov dependency)
Two NLP tasks with sequential data

- **Sequence-to-sequence**
  - Speech recognition using a sound spectrogram
    - decompose sound waves into frequency, amplitude using Fourier transforms
      - “Nineteenth Century”
    - NLP: Named Entity Recognition
      - **Input**: Jim bought 300 shares of Acme Corp. in 2006
      - **NER**: $[\text{Jim}]_{\text{Person}}$ bought 300 shares of $[\text{Acme Corp.}]_{\text{Organization}}$ in $[2006]_{\text{Time}}$
  - Machine Translation: Echte dicke kiste $\rightarrow$ Awesome sauce

- **Sequence-to-symbol**
  - Sentiment:
    - *Best movie ever* $\rightarrow$ Positive
  - Speaker recognition
    - Sound spectrogram $\rightarrow$ Harry
Stationary vs Non-stationary

• Stationary:
  — Data evolves over time but distribution remains same
    • e.g., dependence of current word over previous word remains constant

• Non-stationary:
  — Generative distribution itself changes over time
Making a Sequence of Decisions

• Processes in time, states at time $t$ are influenced by a state at time $t-1$

• Wish to predict next value from previous values
  — e.g., financial forecasting

• Impractical to consider general dependence of future dependence on all previous observations
  — Complexity grows without limit as number of observations increases

• Markov models assume dependence on most recent observations
Markov Model Assuming Independence

• Simplest model: Assume observations are independent
  Graph without links
• To predict whether it rains tomorrow is only based on relative frequency of rainy days
• Ignores influence of whether it rained the previous day
Markov Model

- Most general Markov model for observations \( \{x_n\} \)
- Product rule to express joint distribution of sequence of observations

\[
p(x_1, \ldots x_N) = \prod_{n=1}^{N} p(x_n \mid x_1, \ldots x_{n-1})
\]
First Order Markov Model

- Chain of observations \( \{ x_n \} \)

- Joint distribution for a sequence of \( n \) variables

\[
p(x_1, \ldots, x_N) = p(x_1) \prod_{n=2}^{N} p(x_n | x_{n-1})
\]

- It can be verified (using product rule from above) that

\[
p(x_n | x_1 \ldots x_{n-1}) = p(x_n | x_{n-1})
\]

- If model is used to predict next observation, distribution of prediction will only depend on preceding observation and independent of earlier observations

- Stationarity implies conditional distributions \( p(x_n | x_{n-1}) \) are all equal
Markov Model – Weather

- The weather of a day is one of the following states:
  - State 1: Rainy
  - State 2: Cloudy
  - State 3: Sunny

<table>
<thead>
<tr>
<th>Today</th>
<th>Tomorrow</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Rainy</td>
</tr>
<tr>
<td>Rainy</td>
<td>0.3</td>
</tr>
<tr>
<td>Cloudy</td>
<td>0.2</td>
</tr>
<tr>
<td>Sunny</td>
<td>0.1</td>
</tr>
</tbody>
</table>

The table shows the transition probabilities from one state to another.
Markov Model – Sequence probability

What is the probability that the weather for the next 7 days will be “S-S-R-R-S-C-S”?

Let $O = \{S_3, S_3, S_3, S_1, S_1, S_3, S_2, S_3\}$

Find the probability of $O$, given the model.

$$P(O \mid Model) = P(S_3, S_3, S_3, S_1, S_1, S_3, S_2, S_3 \mid Model)$$

$$= P(S_3) \cdot P(S_3 \mid S_3) \cdot P(S_3 \mid S_3) \cdot P(S_1 \mid S_3)$$

$$\cdot P(S_1 \mid S_1) \cdot P(S_2 \mid S_3) \cdot P(S_3 \mid S_3) \cdot P(S_2 \mid S_2)$$

$$= \pi_3 \cdot a_{33} \cdot a_{33} \cdot a_{31} \cdot a_{11} \cdot a_{13} \cdot a_{32} \cdot a_{23}$$

$$= 1 \cdot (0.8) \cdot (0.8) \cdot (0.1) \cdot (0.4) \cdot (0.3) \cdot (0.1) \cdot (0.2)$$

$$= 1.536 \times 10^{-4}$$
Markov model for spoken word production

• States represent phonemes

• Production of word: “cat”

• Represented by states
  /k/ /a/ /t/

• Transitions from
  • /k/ to /a/
  • /a/ to /t/
  • /t/ to a silent state

• Although only correct cat sound is represented by model, perhaps other transitions can be introduced,
  • eg, /k/ followed by /t/
Second Order Markov Model

- Each observation is influenced by previous two observations
  - Conditional distribution of observation $x_n$ depends on the values of two previous observations $x_{n-1}$ and $x_{n-2}$

\[
p(x_1, \ldots, x_N) = p(x_1)p(x_2 \mid x_1) \prod_{n=3}^{N} p(x_n \mid x_{n-1}, x_{n-2})
\]
$M^{th}$ Order Markov Source

- Conditional distribution for a particular variable depends on previous $M$ variables
- Pay a price for number of parameters
- Discrete variable with $K$ states
  - First order: $p(x_n|x_{n-1})$ needs $K-1$ parameters for each value of $x_{n-1}$ for each of $K$ states of $x_n$ giving $K(K-1)$ parameters
  - $M^{th}$ order will need $K^{M-1}(K-1)$ parameters
Latent Variables

• While Markov models are tractable they are severely limited
• Introduction of latent variables provides a more general framework
• Lead to state-space models
• When latent variables are:
  — Discrete
    • they are called Hidden Markov models
  — Continuous
    • they are linear dynamical systems
Introducing Latent Variables

- Model for sequences not limited by Markov assumption of any order but with limited number of parameters
- For each observation $x_n$, introduce a latent variable $z_n$
- $z_n$ may be of different type or dimensionality to the observed variable
- Latent variables form the Markov chain
- Gives the “state-space model”
Hidden Markov Model

Observations are activities of friend described over telephone
Alternatively from data:

<table>
<thead>
<tr>
<th>Day</th>
<th>M</th>
<th>Tu</th>
<th>W</th>
<th>Th</th>
</tr>
</thead>
<tbody>
<tr>
<td>Temp</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Barometer</td>
<td></td>
<td></td>
<td></td>
<td>16</td>
</tr>
</tbody>
</table>
Conditional Independence with Latent Variables

• Satisfies key assumption that

\[ z_{n+1} \perp z_{n-1} \mid z_n \]

• From d-separation

When latent node \( z_n \) is filled, the only path between \( z_{n-1} \) and \( z_{n+1} \) has a head-to-tail node that is blocked
Jt Distribution with Latent Variables

Latent variables

Observations

• Joint distribution for this model

\[ p(x_1, \ldots, x_N, z_1, \ldots, z_n) = p(z_1) \left[ \prod_{n=2}^{N} p(z_n \mid z_{n-1}) \right] \prod_{n=1}^{N} p(x_n \mid z_n) \]

• There is always a path between any \( x_n \) and \( x_m \) via latent variables which is never blocked

• Thus predictive distribution \( p(x_{n+1} \mid x_1, \ldots, x_n) \) for observation \( x_{n+1} \) does not exhibit conditional independence properties and is hence dependent on all previous observations
Two Models Described by Graph

1. Hidden Markov Model: If latent variables are discrete:
   Observed variables in a HMM may be discrete or continuous

2. Linear Dynamical Systems: If both latent and observed variables are Gaussian
