Topics in Linear Classification using Probabilistic Discriminative Models

• Generative vs Discriminative
  1. Fixed basis functions
  2. Logistic Regression (two-class)
  3. Iterative Reweighted Least Squares (IRLS)
  4. Multiclass Logistic Regression
  5. Probit Regression
  6. Canonical Link Functions
Topics in Logistic Regression

- Logistic Sigmoid and Logit Functions
- Parameters in discriminative approach
- Determining logistic regression parameters
  - Error function
  - Gradient of error function
  - Simple sequential algorithm
  - An example
- Generative vs Discriminative Training
  - Naive Bayes vs Logistic Regression
Logistic Sigmoid and Logit Functions

- **In two-class case**, posterior of class $C_1$ can be written as a logistic sigmoid of feature vector $\phi = [\phi_1, \ldots, \phi_M]^T$

  \[ p(C_1|\phi) = y(\phi) = \sigma(w^T\phi) \]

  with \( p(C_2|\phi) = 1 - p(C_1|\phi) \)

  Here $\sigma(.)$ is the logistic sigmoid function
  - Known as logistic regression in statistics
    - Although a model for classification rather than for regression

- **Logit function**:
  - It is the log of the odds ratio
    - It links the probability to the predictor variables

**Properties**:

- **A. Symmetry**
  \[ \sigma(-a) = 1 - \sigma(a) \]

- **B. Inverse**
  \[ a = \ln(\sigma/1-\sigma) \]
  known as logit.
  Also known as log odds since it is the ratio
  \[ \ln[p(C_1|\phi)/p(C_2|\phi)] \]

- **C. Derivative**
  \[ d\sigma/da = \sigma(1-\sigma) \]
Fewer Parameters in Linear Discriminative Model

- **Discriminative approach (Logistic Regression)**
  - For $M$ -dim feature space $\phi$:
    - $M$ adjustable parameters
- **Generative based on Gaussians (Bayes/NB)**
  - $2M$ parameters for mean
  - $M(M+1)/2$ parameters for shared covariance matrix
  - Two class priors
  - Total of $M(M+5)/2 + 1$ parameters
    - Grows quadratically with $M$
  - If features assumed independent (naïve Bayes) still needs $M+3$ parameters
Determining Logistic Regression parameters

• Maximum Likelihood Approach for Two classes
• For a data set \((\phi_n, t_n)\) where \(t_n \in \{0,1\}\) and \(\phi_n = \phi(x_n), n = 1, \ldots, N\)

• Likelihood function can be written as

\[
p(t \mid w) = \prod_{n=1}^{N} y_n^{t_n} \left\{1 - y_n\right\}^{1-t_n}
\]

where \(t = (t_1, \ldots, t_N)^T\) and \(y_n = p(C_1 | \phi_n)\)

\(y_n\) is the probability that \(t_n = 1\)
Error Fn for Logistic Regression

- **Likelihood function is**
  
  $$p(t \mid w) = \prod_{n=1}^{N} y_n^t \{1 - y_n\}^{1-t_n}$$

- **By taking negative logarithm we get the Cross-entropy Error Function**
  
  $$E(w) = -\ln p(t \mid w) = -\sum_{n=1}^{N} \left\{ t_n \ln y_n + (1 - t_n) \ln(1 - y_n) \right\}$$

  where $$y_n = \sigma(a_n)$$ and $$a_n = w^T \phi_n$$

- **We need to minimize** $$E(w)$$
  
  At its minimum, derivative of $$E(w)$$ is zero
  
  So we need to solve for $$w$$ in the equation
  
  $$\nabla E(w) = 0$$
**What is Cross-entropy?**

- **Entropy of** \( p(x) \) **is defined as**
  
  \[
  H(p) = - \sum_x p(x) \log p(x)
  \]

  - If \( p(x=1|t)=t \) and \( p(x=0|t)=1-t \) then we can write
    \[
    p(x) = tx(1-t)^{1-x}
    \]
  
  - Then Entropy of \( p(x) \) is \( H(p) = t \log t + (1-t) \log (1-t) \)

- **Cross entropy of** \( p(x) \) **and** \( q(x) \) **is defined as**
  
  \[
  H(p,q) = - \sum_x p(x) \log q(x)
  \]

  - If \( q(x=1|y)=y \) then \( H(p,q) = t \log y + (1-t) \log (1-y) \)

- **In general** \( H(p,q) = H(p) + D_{KL}(p||q) \)
  
  - where
    
    \[
    D_{KL}(p,q) = - \sum_x p(x) \log \frac{p(x)}{q(x)}
    \]
Gradient of Error Function

Error function

\[ E(w) = -\ln p(t \mid w) = -\sum_{n=1}^{N} \{ t_n \ln y_n + (1 - t_n) \ln (1 - y_n) \} \]

where \( y_n = \sigma (w^T \phi_n) \)

Using Derivative of logistic sigmoid \( d\sigma / da = \sigma (1 - \sigma) \)

Gradient of the error function

\[ \nabla E(w) = \sum_{n=1}^{N} (y_n - t_n) \phi_n \]

Proof of gradient expression

Let \( z = z_1 + z_2 \)
where \( z_1 = t \ln \sigma (w\phi) \) and \( z_2 = (1 - t) \ln [1 - \sigma (w\phi)] \)

\[ \frac{dz_1}{dw} = \frac{t \sigma (w\phi) [1 - \sigma (w\phi)] \phi}{\sigma (w\phi)} \]
and

\[ \frac{dz_2}{dw} = \frac{(1 - t) \sigma (w\phi) [1 - \sigma (w\phi)] (-\phi)}{[1 - \sigma (w\phi)]} \]

Therefore \( \frac{dz}{dw} = (\sigma (w\phi) - t) \phi \)

Using \( \frac{d}{dx} (\ln ax) = \frac{a}{x} \)
Simple Sequential Algorithm

- Given Gradient of error function
  \[ \nabla E(w) = \sum_{n=1}^{N} (y_n - t_n) \phi_n \]
  where \( y_n = \sigma(w^T \phi_n) \)

- Solve using an iterative approach
  \[ w^{\tau+1} = w^{\tau} - \eta \nabla E_n \]

- where
  \[ \nabla E_n = (y_n - t_n) \phi_n \]

Takes precisely same form as Gradient of Sum-of-squares error for linear regression

Samples are presented one at a time in which each weight vector is updated.
Python Code for Logistic Regression

Sigmoid function to produce value between 0 and 1

```python
def sigmoid(z):
    return (1 / (1 + np.exp(-z)))
```

Loss and Cost function

Loss function is the loss for a training example

\[
L(p, y) = -(y \log p + (1 - y) \log (1 - p))
\]

Cost is the loss for whole training set

\[
\text{Cost} = \sum_{k=1}^{m} L(p, y)
\]

Updating weights and biases

\[ p \text{ is our prediction and } y \text{ is correct value} \]

\[
b := b - \alpha db
\]
\[
w := w - \alpha dw
\]

Finding \(db\) and \(dw\)

Derivative wrt \(p \rightarrow \) Derivative wrt \(z\).
Logistic Regression Code in Python

import sklearn.datasets
import matplotlib.pyplot as plt
import numpy as np
X, Y = sklearn.datasets.make_moons(n_samples=500, noise=.2)
X, Y = X.T, Y.reshape(1, Y.shape[0])
epochs = 1000
learningrate = 0.01
def sigmoid(z):
    return 1 / (1 + np.exp(-z))
losstrack = []
m = X.shape[1]
w = np.random.randn(X.shape[0], 1)*0.01
b = 0
for epoch in range(epochs):
    z = np.dot(w.T, X) + b
    p = sigmoid(z)
    cost = -np.sum(np.multiply(np.log(p), Y) + np.multiply((1 - Y), np.log(1 - p)))/m
    losstrack.append(np.squeeze(cost))
    dz = p-Y
    dw = (1 / m) * np.dot(X, dz.T)
    db = (1 / m) * np.sum(dz)
    w = w - learningrate * dw
    b = b - learningrate * db
plt.plot(losstrack)

Prediction: From the code above, you find $p$. It will be between 0 and 1.
ML solution can over-fit

• Severe over-fitting for linearly separable data
  – Because ML solution occurs at \( \sigma = 0.5 \)
    • With \( \sigma > 0.5 \) and \( \sigma < 0.5 \) for the two classes
    • Solution equivalent to \( a = w^T \phi = 0 \)
  – Logistic sigmoid becomes infinitely steep
    • A Heavyside step function \( ||w|| \) goes to \( \infty \)

– Solution
  • Penalizing wts
  • Recall in linear regression

\[
\nabla E_n = - \sum_{n=1}^{N} \left\{ t_n - w^T \phi(x_n) \right\} \phi(x_n)^T
\]

without reg

\[
\nabla E_n = \left[ - \sum_{n=1}^{N} \left\{ t_n - w^T \phi(x_n) \right\} \phi(x_n)^T \right] + \lambda |w|
\]

with reg
An Example of 2-class Logistic Regression

• Input Data

\begin{align*}
C_1 &= \\
&=
\begin{bmatrix}
3.7000 & 3.0000 \\
3.2000 & 3.5000 \\
3.5000 & 5.0000 \\
3.6000 & 4.5000 \\
3.5000 & 4.0000 \\
\end{bmatrix}
\end{align*}

\begin{align*}
C_2 &= \\
&=
\begin{bmatrix}
1.1000 & -1.3000 \\
0.2000 & 0.5000 \\
1.5000 & 0.3000 \\
0.2000 & 0.8000 \\
1.0000 & 0.7000 \\
\end{bmatrix}
\end{align*}

\[\phi_0(x) = 1, \text{ dummy feature}\]
Initial Weight Vector, Gradient and Hessian (2-class)

- Weight vector
  
  $W =
  \begin{bmatrix}
  0.1117 \\
  0.1363 \\
  0.6787
  \end{bmatrix}$

- Gradient
  
  $\Delta_E =
  \begin{bmatrix}
  0 \\
  6.7500 \\
  9.5000
  \end{bmatrix}$

- Hessian
  
  $H =
  \begin{bmatrix}
  3.5000 & 5.3750 & 5.2500 \\
  5.3750 & 17.4825 & 17.4950 \\
  5.2500 & 17.4950 & 22.4150
  \end{bmatrix}$
Final Weight Vector, Gradient and Hessian (2-class)

- **Weight Vector**
  
  \[
  W = \\
  \begin{bmatrix}
  704.5915 \\
  -20.9086 \\
  -337.6170
  \end{bmatrix}
  \]

- **Gradient**
  
  \[
  \Delta E = \\
  \begin{bmatrix}
  -12.2617 \\
  -1.6321 \\
  4.9025
  \end{bmatrix}
  \]

- **Hessian**
  
  \[
  H = \\
  \begin{bmatrix}
  1.0000 & 0.0000 & 0.0000 \\
  0.0000 & 1.0000 & 0.0000 \\
  0.0000 & 0.0000 & 1.0000
  \end{bmatrix}
  \]

Number of iterations: 10

Error (Initial and Final): 15.0642, 1.0000e-009
Generative vs Discriminative Training

Variables $x = \{x_1, \ldots, x_M\}$ and classifier target $y$

1. **Generative:** estimate parameters of variables independently

   - **Naïve Bayes**
     - For classification: Determine joint:
       $$ p(y, x) = p(y) \prod_{i=1}^{M} p(x_i | y) $$
     - From joint get required conditional $p(y | x)$
     
   - **Simple estimation**
     - Independently estimate $M$ sets of parameters
     - But independence is usually false
     - We can estimate $M(M+1)/2$ covariance matrix

2. **Discriminative:** estimate joint parameters $w_i$

   - **Potential Functions (log-linear)**
     - $\phi_i(x, y) = \exp\{w_i x_i I\{y=1\}\}$,
     - $\phi_0(y) = \exp\{w_0 I\{y=1\}\}$
     - I has value 1 when $y=1$, else 0

   - **Naïve Markov**
     
   - **Logistic Regression**
     - For classification:
       - **Unnormalized**
         $$ \tilde{P}(y = 1 | x) = \exp\{w_0 + \sum_{i=1}^{M} w_i x_i\} $$
       - **Normalized**
         $$ P(y = 1 | x) = \text{sigmoid}\left(w_0 + \sum_{i=1}^{M} w_i x_i\right) $$
     - where $\text{sigmoid}(z) = \frac{e^z}{1+e^z}$

   - **Jointly optimize $M$ parameters**
     - More complex estimation but correlations accounted for
     - Can use much richer features:
       - Edges, image patches sharing same pixels

   - **multiclass**
     $$ p(y_i | \phi) = \frac{\exp(a_i)}{\sum_j \exp(a_j)} $$
     where $a_j = w_j^T \phi$
Logistic Regression is a special architecture of a neural network
**Binary Classification**

1: CAT  
0: NOT CAT

**Logistic Regression as a Neural Net**

**Finding the Minimum with Gradient Descent**

1. Find the downhill direction (using derivatives)  
2. Walk (update w & b) at a small learning rate  
3. Repeat until you reach bottom (converge)

**Putting it all together**

THE TASK IS TO LEARN w & b BUT HOW?

A: Optimize how good the guess is by minimizing the error between guess (y) and truth (ŷ)

- Loss = L(ŷ, y)  
- Cost = J(w, b) = \(\frac{1}{m} \sum_{i=1}^{m} L(y_i, y_i^{(i)})\)
- Cost = Loss for the entire dataset

\[ z(x) = w^T x + b \]
\[ \hat{y} = a(z) = \sigma(z) \]

Cost = Loss for the entire dataset

1. Forward propagation  
2. Backward propagation  
3. Calculate \( \nabla J(w, b) \)  
4. Update \( w \) and \( b \)
