Iterative Reweighted Least Squares

Sargur N. Srihari
University at Buffalo, State University of New York
USA
Topics in Linear Classification using Probabilistic Discriminative Models

- Generative vs Discriminative
  1. Fixed basis functions in linear classification
  2. Logistic Regression (two-class)
  3. Iterative Reweighted Least Squares (IRLS)
  4. Multiclass Logistic Regression
  5. Probit Regression
  6. Canonical Link Functions
Topics in IRLS

- Linear and Logistic Regression
- Newton-Raphson Method
- Hessian
- IRLS for Linear Regression
- IRLS for Logistic Regression
- Numerical Example
- Hessian in Deep Learning
Recall Linear Regression

- Assuming Gaussian noise
  \[ p(t|\mathbf{x},\mathbf{w},\beta) = N(t|y(\mathbf{x},\mathbf{w}),\beta^{-1}) \]
- And a linear model
  \[ y(\mathbf{x},\mathbf{w}) = \sum_{j=0}^{M-1} w_j \phi_j(\mathbf{x}) = \mathbf{w}^T \phi(\mathbf{x}) \]
- Likelihood has the form
  \[
p(t|\mathbf{X},\mathbf{w},\beta) = \prod_{n=1}^{N} N(t_n|\mathbf{w}^T \phi(\mathbf{x}_n),\beta^{-1})\]
- Log-likelihood becomes
  \[
  \ln p(t|\mathbf{w},\beta) = \sum_{n=1}^{N} \ln N(t_n|\mathbf{w}^T \phi(\mathbf{x}_n),\beta^{-1}) = \frac{N}{2} \ln \beta - \frac{N}{2} \ln 2\pi - \beta E_D(\mathbf{w})
  \]
- Which is quadratic in input
- Derivative has the form
  \[
  \nabla \ln p(t|\mathbf{w},\beta) = \beta \sum_{n=1}^{N} \left\{ t_n - \mathbf{w}^T \phi(\mathbf{x}_n) \right\} \phi(\mathbf{x}_n)^T
  \]
- Setting equal to zero and solving we get
  \[
  \mathbf{w}_{ML} = \Phi^+ \mathbf{t} \quad \Phi^+ = (\Phi^T \Phi)^{-1} \Phi^T
  \]

\[
\Phi = \begin{pmatrix}
\phi_0(x_1) & \phi_1(x_1) & \ldots & \phi_{M-1}(x_1) \\
\phi_0(x_2) \\
\phi_0(x_N) & \phi_{M-1}(x_N)
\end{pmatrix}
\]
Linear and Logistic Regression

• In linear regression there is a closed-form max likelihood solution for determining $\mathbf{w}$ on the assumption of Gaussian noise model
  
  $$E_D(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^{N} \left\{ t_n - \mathbf{w}^T \phi(x_n) \right\}^2$$

• Due to quadratic dependence of log-likelihood on $\mathbf{w}$

$$\mathbf{w}_{ML} = \Phi^+ \mathbf{t}$$

• For logistic regression: No closed-form maximum likelihood solution
  
  • Due to nonlinearity of logistic sigmoid

$$E(\mathbf{w}) = -\ln p(t \mid \mathbf{w}) = -\sum_{n=1}^{N} \left\{ t_n \ln y_n + (1 - t_n) \ln(1 - y_n) \right\}$$

  $$y_n = \sigma(\mathbf{w}^T \phi_n)$$

• But departure from quadratic is not substantial
  
  • Error function is concave, i.e., unique minimum
What is IRLS?

• An iterative method to find solution $w^*$
  – for linear regression and logistic regression
    • assuming least squares objective

• While simple gradient descent has the form
  \[ w^{(new)} = w^{(old)} - \eta \nabla E(w) \]

• IRLS uses the second derivative and has the form
  \[ w^{(new)} = w^{(old)} - H^{-1} \nabla E(w) \]
  • It is derived from Newton-Raphson method
    • where $H$ is the Hessian matrix whose elements are the second derivatives of $E(w)$ wrt $w$
Newton-Raphson Method (1-D)

- Based on second derivatives
  - Derivative of a function at $x$ is the slope of its tangent at that point
- Illustration of 2\textsuperscript{nd} and higher derivatives
  - Derivatives of Gaussian $p(x) \sim N(0, \sigma)$

\[
\frac{\partial}{\partial x} \left[ \frac{1}{\sqrt{2\pi}\sigma} e^{-x^2/(2\sigma^2)} \right] = \frac{-x}{\sqrt{2\pi}\sigma^3} e^{-x^2/(2\sigma^2)} = \frac{-x}{\sigma^2} \quad p(x)
\]
\[
\frac{\partial^2}{\partial x^2} \left[ \frac{1}{\sqrt{2\pi}\sigma} e^{-x^2/(2\sigma^2)} \right] = \frac{1}{\sqrt{2\pi}\sigma^3} \left( -\sigma^2 + x^2 \right) e^{-x^2/(2\sigma^2)} = \frac{-\sigma^2 + x^2}{\sigma^4} \quad p(x)
\]
\[
\frac{\partial^3}{\partial x^3} \left[ \frac{1}{\sqrt{2\pi}\sigma} e^{-x^2/(2\sigma^2)} \right] = \frac{1}{\sqrt{2\pi}\sigma^7} \left( 3\sigma^2 - x^3 \right) e^{-x^2/(2\sigma^2)} = \frac{-3\sigma^2 - x^3}{\sigma^6} \quad p(x)
\]

Since we are solving for derivative of $E(w)$
Need second derivative
Second derivative measures curvature

- **Derivative of a derivative**
- **Quadratic functions with different curvatures**

Dashed line is value of cost function predicted by gradient alone

Negative curvature: Decrease is faster than predicted by Gradient Descent.

No curvature: Gradient predicts decrease correctly.

Positive curvature: Decrease is slower than expected. Actually increases.
Beyond Gradient: Jacobian and Hessian matrices

• Sometimes we need to find all derivatives of a function whose input and output are both vectors.

• If we have function \( f: \mathbb{R}^m \rightarrow \mathbb{R}^n \)
  – Then the matrix of partial derivatives is known as the Jacobian matrix \( J \) defined as

\[
J_{i,j} = \frac{\partial}{\partial x_j} f(x)_i
\]
Second derivative

• Derivative of a derivative
• For a function \( f: \mathbb{R}^n \rightarrow \mathbb{R} \) the derivative \( \frac{\partial}{\partial x_i} \) of the derivative of \( f \) wrt \( x_j \) is denoted as \( \frac{\partial^2 f}{\partial x_i \partial x_j} \)
• In a single dimension we can denote it by \( f''(x) \)
• Tells us how the first derivative will change as we vary the input
• This important as it tells us whether a gradient step will cause as much of an improvement as based on gradient alone
Hessian

• Second derivative with many dimensions

\[ H(f)(x) \]

\[ \frac{\partial^2}{\partial x_i \partial x_j} f(x) \]

• Hessian is the Jacobian of the gradient

• Hessian matrix is symmetric, i.e., \( H_{i,j} = H_{j,i} \)
  
  - anywhere that the second partial derivatives are continuous

  - So the Hessian matrix can be decomposed into a set of real eigenvalues and an orthogonal basis of eigenvectors

  • Eigenvalues of \( H \) are useful to determine learning rate as seen in next two slides
Role of eigenvalues of Hessian

• Second derivative in direction $d$ is $d^T H d$
  – If $d$ is an eigenvector, second derivative in that direction is given by its eigenvalue
  – For other directions, weighted average of eigenvalues (weights of 0 to 1, with eigenvectors with smallest angle with $d$ receiving more value)

• Maximum eigenvalue determines maximum second derivative and minimum eigenvalue determines minimum second derivative
Learning rate from Hessian

- Taylor’s series of $f(x)$ around current point $x^{(0)}$

$$f(x) \approx f(x^{(0)}) + (x - x^{(0)})^T g + \frac{1}{2} (x - x^{(0)})^T H(x - x^{(0)})$$

- where $g$ is the gradient and $H$ is the Hessian at $x^{(0)}$

- If we use learning rate $\varepsilon$ the new point $x$ is given by $x^{(0)} - \varepsilon g$. Thus we get

$$f(x^{(0)} - \varepsilon g) \approx f(x^{(0)}) - \varepsilon g^T g + \frac{1}{2} \varepsilon^2 g^T H g$$

- There are three terms:
  - original value of $f$,
  - expected improvement due to slope, and
  - correction to be applied due to curvature

- Solving for step size when correction is least gives

$$\varepsilon^* \approx \frac{g^T g}{g^T H g}$$
Another 2\textsuperscript{nd} Derivative Method

- Using Taylor’s series of $f(x)$ around current $x^{(0)}$

\[
f(x) \approx f(x^{(0)}) + (x - x^{(0)})^T \nabla_x f(x^{(0)}) + \frac{1}{2} (x - x^{(0)})^T H(f)(x - x^{(0)})(x - x^{(0)})
\]

- solve for the critical point of this function to give

\[
x^* = x^{(0)} - H(f)(x^{(0)})^{-1} \nabla_x f(x^{(0)})
\]

- When $f$ is a quadratic (positive definite) function use solution to jump to the minimum function directly
- When not quadratic apply solution iteratively

- Can reach critical point much faster than gradient descent
- But useful only when nearby point is a minimum
Two applications of IRLS

- IRLS is applicable to both Linear Regression and Logistic Regression.
- We discuss both, for each we need:
  1. Model
     \[ y(x, w) = \sum_{j=0}^{M-1} w_j \phi_j(x) = w^T \phi(x) \]
     \[ p(C_1 | \phi) = y(\phi) = \sigma(w^T \phi) \]
  2. Objective function \( E(w) \)
     - Linear Regression: Sum of Squared Errors
     - Logistic Regression: Bernoulli Likelihood Function
  3. Gradient
     \[ \nabla E(w) \]
  4. Hessian
     \[ H = \nabla \nabla E(w) \]
  5. Newton-Raphson update
     \[ w^{(\text{new})} = w^{(\text{old})} - H^{-1} \nabla E(w) \]
IRLS for Linear Regression

1. Model: \[ y(x, w) = \sum_{j=0}^{N-1} w_j \phi_j(x) = w^T \phi(x) \]

2. Error Function: Sum of Squares:
   \[ E(w) = \frac{1}{2} \sum_{n=1}^{N} \left( t_n - w^T \phi(x_n) \right)^2 \]
   for data set \( X = \{ x_n, t_n \} \) \( n=1 \ldots N \)

3. Gradient of Error Function is:
   \[ \nabla E(w) = \sum_{n=1}^{N} (w^T \phi_n - t_n) \phi_n \]
   \[ = \Phi^T \Phi w - \Phi^T t \]

   where \( \Phi \) is the \( N \times M \) design matrix whose \( n^{th} \) row is given by \( \phi_n \)

4. Hessian is:
   \[ H = \nabla \nabla E(w) = \sum_{n=1}^{N} \phi_n \phi_n^T = \Phi^T \Phi \]

5. Newton-Raphson Update:
   \[ w^{(new)} = w^{(old)} - H^{-1} \nabla E(w) \]

Substituting: \[ H = \Phi^T \Phi \] and \[ \nabla E(w) = \Phi^T \Phi w - \Phi^T t \]

\[
\begin{align*}
    w^{(new)} &= w^{(old)} - (\Phi^T \Phi)^{-1} (\Phi^T \Phi w^{(old)} - \Phi^T t) \\
    &= (\Phi^T \Phi)^{-1} \Phi^T t
\end{align*}
\]

which is the standard least squares solution

Since it is independent of \( w \), Newton-Raphson gives exact solution in one step
IRLS for Logistic Regression

1. **Model:** \( p(C_1 | \phi) = y(\phi) = \sigma (w^T \phi) \)  
   Likelihood: \( p(t | w) = \prod_{n=1}^{N} y_n^{t_n} \left( 1 - y_n \right)^{1-t_n} \)  
   for data set \( \{\phi_n, t_n\} \), \( t_n \in \{0,1\} \), \( y_n = \phi(x_n) \)

2. **Objective Function:** Negative log-likelihood:  
   Cross-entropy error function

3. **Gradient of Error Function is:**  
   \( \nabla E(w) = \sum_{n=1}^{N} (y_n - t_n) \phi_n = \Phi^T(y - t) \)  
   where \( \Phi \) is the \( N \times M \) design matrix whose \( n^{th} \) row is given by \( \phi_n^T \)

4. **Hessian is:**  
   \( H = \nabla \nabla E(w) = \sum_{n=1}^{N} y_n(1-y_n)\phi_n\phi_n^T = \Phi^T R \Phi \)  
   \( R \) is \( N \times N \) diagonal matrix with elements  
   \( R_{nn} = y_n(1-y_n) = w^T \phi_n(1-w^T \phi_n) \)  
   Hessian is not constant and depends on \( w \) through \( R \). Since \( H \) is positive-definite (i.e., for arbitrary \( u \), \( u^T H u > 0 \)) error function is a concave function of \( w \) and so has a unique minimum

5. **Newton-Raphson Update:**  
   \( w^{(new)} = w^{(old)} - H^{-1} \nabla E(w) \)  
   Substituting \( H = \Phi^T R \Phi \) and \( \nabla E(w) = \Phi^T (y - t) \)  
   \( w^{(new)} = w^{(old)} - (\Phi^T R \Phi)^{-1} \Phi^T (y - t) \)  
   \( = (\Phi^T R \Phi)^{-1} \{ \Phi w^{(old)} - \Phi (y - t) \} \)  
   \( = (\Phi^T R \Phi)^{-1} \Phi^T R z \)  
   where \( z \) is a \( N \)-dimensional vector with elements  
   \( z = \Phi w^{(old)} R^{-1} (y - t) \)  
   Update formula is a set of normal equations.  
   Since Hessian depends on \( w \) apply them iteratively each time using the new weight vector
Initial Weight Vector, Gradient and Hessian (2-class)

- Weight vector
  \[
  W = \\
  \begin{bmatrix}
  0.1117 \\
  0.1363 \\
  0.6787 \\
  \end{bmatrix}
  \]

- Gradient
  \[
  \Delta E = \\
  \begin{bmatrix}
  0 \\
  6.7500 \\
  9.5000 \\
  \end{bmatrix}
  \]

- Hessian
  \[
  H = \\
  \begin{bmatrix}
  3.5000 & 5.3750 & 5.2500 \\
  5.3750 & 17.4825 & 17.4950 \\
  5.2500 & 17.4950 & 22.4150 \\
  \end{bmatrix}
  \]
Final Weight Vector, Gradient and Hessian (2-class)

- **Weight Vector**
  
  \[
  W = \\
  \begin{bmatrix}
  704.5915 \\
  -20.3086 \\
  -337.6170 \\
  \end{bmatrix}
  \]

- **Gradient**
  
  \[
  \text{Delta}_E = \\
  \begin{bmatrix}
  -12.3917 \\
  -1.6321 \\
  4.9025 \\
  \end{bmatrix}
  \]

- **Hessian**
  
  \[
  H = \\
  \begin{bmatrix}
  1.0000 & 0.0000 & 0.0000 \\
  0.0000 & 1.0000 & 0.0000 \\
  0.0000 & 0.0000 & 1.0000 \\
  \end{bmatrix}
  \]

Number of iterations: 10

Error (Initial and Final): 15.0642, 1.0000e-009
Hessian in Deep Learning

• The second derivative can be used to determine whether a critical point is a local minimum, maximum or a saddle point
  – On a critical point $f'(x) = 0$
  – When $f''(x) > 0$ the first derivative $f'(x)$ increases as we move to the right and decreases as we move left
    • We conclude that $x$ is a local minimum
  – For local maximum, $f'(x) = 0$ and $f''(x) < 0$
  – When $f''(x) = 0$ test is inconclusive: $x$ may be a saddle point or part of a flat region
Multidimensional Second derivative test

- In multiple dimensions, we need to examine second derivatives of all dimensions
- Eigendecomposition generalizes the test
- Test eigenvalues of Hessian to determine whether critical point is a local maximum, local minimum or saddle point
- When $H$ is positive definite (all eigenvalues are positive) the point is a local minimum
- Similarly negative definite implies a maximum
Saddle point

• Contains both positive and negative curvature
• Function is $f(x) = x_1^2 - x_2^2$

- Along axis $x_1$, function curves upwards: this axis is an eigenvector of $H$ and has a positive value
- Along $x_2$, function curves downwards; its direction is an eigenvector of $H$ with negative eigenvalue
- At a saddle point eigenvalues are both positive and negative
