Mixtures of Gaussians

Sargur Srihari
srihari@cedar.buffalo.edu
9. Mixture Models and EM

0. Mixture Models Overview
1. K-Means Clustering
2. Mixtures of Gaussians
3. An Alternative View of EM
4. The EM Algorithm in General
Topics in Mixtures of Gaussians

- Goal of Gaussian Mixture Modeling
- Latent Variables
- Maximum Likelihood
- EM for Gaussian Mixtures
GMMs and Latent Variables

• A GMM is a linear superposition of Gaussian components
  – Provides a richer class of density models than the single Gaussian

• We formulate a GMM in terms of discrete latent variables
  – This provides deeper insight into this distribution
  – Serves to motivate the EM algorithm
    • Which gives a maximum likelihood solution to no. of components and their means/covariances
Latent Variable Representation

- Gaussian mixture distribution is written as
  - a linear superposition of \( K \) Gaussian components:
    \[
    p(x) = \sum_{k=1}^{K} \pi_k N(x \mid \mu_k, \Sigma_k)
    \]
  - Represent \( K \) by a \( K \)-dimensional binary variable \( z \)
    - Using 1-of-\( K \) representation (one-hot vector)
    - Let \( z = z_1, \ldots, z_K \) whose elements are
      \[z_k \in \{0, 1\} \text{ and } \sum_k z_k = 1\]
    - \( K \) possible states of \( z \) corresponding to \( K \) components

\[
\begin{array}{c|cc}
  k & 1 & 2 \\
  \pi_k & 0.4 & 0.6 \\
  \mu_k & -28 & 1.86 \\
  \sigma_k & 0.48 & 0.88 \\
\end{array}
\]

\[
\begin{array}{c|cccc}
  k & 1 & 2 & 3 \\
  z & 100 & 010 & 001 \\
\end{array}
\]
Goal of Gaussian Mixture Modeling

• A linear superposition of Gaussians in the form

\[ p(x) = \sum_{k=1}^{K} \pi_k \mathcal{N}(x \mid \mu_k, \Sigma_k) \]

• Goal of Modeling:
  • Find maximum likelihood parameters \( \pi_k, \mu_k, \Sigma_k \)
  • Examples of data sets and models

1-D data, \( K=2 \) subclasses

<table>
<thead>
<tr>
<th>( k )</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \pi )</td>
<td>0.4</td>
<td>0.6</td>
</tr>
<tr>
<td>( \mu )</td>
<td>-28</td>
<td>1.86</td>
</tr>
<tr>

<td>0.48</td>
<td>0.88</td>
</tr>
</tbody>
</table>

2-D data, \( K=3 \)

Each data point is associated with a subclass \( k \) with probability \( \pi_k \)
Joint Distribution

- Define joint distribution of latent variable and observed variable
  \[ p(x, z) = p(x | z) \cdot p(z) \]
  - \( x \) is observed variable
  - \( z \) is the hidden or missing variable
  - Marginal distribution \( p(z) \)
  - Conditional distribution \( p(x | z) \)
Graphical Representation of Mixture Model

• The joint distribution $p(x, z)$ is represented in the form $p(z)p(x|z)$

Latent variable $z = [z_1, \ldots, z_K]$ represents subclass

Observed variable $x$

– We now specify marginal $p(z)$ and conditional $p(x|z)$

• Using them we specify $p(x)$ in terms of observed and latent variables
Specifying the marginal $p(z)$

- Associate a probability with each component $z_k$
  - Denote $p(z_k = 1) = \pi_k$ where parameters $\{\pi_k\}$ satisfy $0 \leq \pi_k \leq 1$ and $\sum_k \pi_k = 1$

- Because $z$ uses 1-of-$K$ it follows that

$$p(z) = \prod_{k=1}^{K} \pi_k^{z_k}$$

- Since $z_k \in \{0,1\}$ and components of $z$ are mutually exclusive and hence are independent

With one component
$$p(z_1) = \pi_1^{z_1}$$

With two components
$$p(z_1, z_2) = \pi_1^{z_1} \pi_2^{z_2}$$
Specifying the Conditional \( p(x|z) \)

- For a particular component (value of \( z \))
  \[
p(x | z_k = 1) = N(x | \mu_k, \Sigma_k)
  \]
- Thus \( p(x|z) \) can be written in the form
  \[
p(x | z) = \prod_{k=1}^{K} N(x | \mu_k, \Sigma_k)^{z_k}
  \]
  - Due to the exponent \( z_k \) all product terms except for one equal one
Marginal distribution $p(x)$

- The joint distribution $p(x,z)$ is given by $p(z)p(x|z)$
- Thus marginal distribution of $x$ is obtained by summing over all possible states of $z$ to give

$$p(x) = \sum_z p(z)p(x | z) = \sum_z \prod_{k=1}^{K} \pi_k z_k N(x | \mu_k, \Sigma_k)^{z_k} = \sum_{k=1}^{K} \pi_k N(x | \mu_k, \Sigma_k)$$

  - Since $z_k \in \{0,1\}$

- This is the standard form of a Gaussian mixture
Value of Introducing Latent Variable

- If we have observations $x_1, \ldots, x_N$
- Because marginal distribution is in the form
  \[ p(x) = \sum_z p(x, z) \]
  - It follows that for every observed data point $x_n$ there is a corresponding latent vector $z_n$, i.e., its sub-class
- Thus we have found a formulation of Gaussian mixture involving an explicit latent variable
  - We are now able to work with joint distribution $p(x, z)$ instead of marginal $p(x)$
- Leads to significant simplification through introduction of expectation maximization
Another conditional probability (Responsibility)

• In EM $p(z | x)$ plays a role

• The probability $p(z_k=1 | x)$ is denoted $\gamma(z_k)$
  
  – From Bayes theorem

  \[
  \gamma(z_k) \equiv p(z_k = 1 | x) = \frac{p(z_k = 1)p(x | z_k = 1)}{\sum_{j=1}^{K} p(z_j = 1)p(x | z_j = 1)} \\
  = \frac{\pi_k N(x | \mu_k, \Sigma_k)}{\sum_{j=1}^{K} \pi_j N(x | \mu_j, \Sigma_j)}
  \]

  – View $p(z_k = 1) = \pi_k$ as prior probability of component $k$ and $\gamma(z_k) = p(z_k = 1 | x)$ as the posterior probability

it is also the responsibility that component $k$ takes for explaining the observation $x$
Plan of Discussion

• Next we look at
  1. How to get data from a mixture model synthetically and then
  2. Given a data set \( \{x_1, \ldots, x_N\} \) how to model the data using a mixture of Gaussians
Synthesizing data from mixture

- Use ancestral sampling
  - Start with lowest numbered node and draw a sample,
    - Generate sample of $z$, called $\hat{z}$
    - Move to successor node and draw a sample given the parent value, etc.
    - Then generate a value for $x$ from conditional $p(x | \hat{z})$
  - Samples from $p(x, z)$ are plotted according to value of $x$ and colored with value of $z$
  - Samples from marginal $p(x)$ obtained by ignoring values of $z$
Illustration of responsibilities

• Evaluate for every data point
  – Posterior probability of each component
  – Responsibilities $\gamma(z_{nk})$ associated with data point $x_n$ and component $k$
  – Color using proportion of red, blue and green ink
    • If for a data point $\gamma(z_{n1}) = 1$ it is colored red
    • If for another point $\gamma(z_{n2}) = \gamma(z_{n3}) = 0.5$ it has equal blue and green and will appear as cyan
Maximum Likelihood for GMM

- We wish to model data set \( \{x_1, \ldots x_N\} \) using a mixture of Gaussians (\( N \) items each of dimension \( D \)).
- Represent by \( N \times D \) matrix \( X \)
  - \( n^{\text{th}} \) row is given by \( x_n^T \)
- Represent \( N \) latent variables with \( N \times K \) matrix \( Z \)
  - \( n^{\text{th}} \) row is given by \( z_n^T \)
- Goal is to state the likelihood function
  - so as to estimate the three sets of parameters
  - by maximizing the likelihood
Graphical representation of GMM

- For a set of i.i.d. data points \( \{ \mathbf{x}_n \} \) with corresponding latent points \( \{ \mathbf{z}_n \} \) where \( n=1,..,N \)
- Bayesian Network for \( p(\mathbf{X}, \mathbf{Z}) \) using plate notation
  - \( N \times D \) matrix \( \mathbf{X} \)
  - \( N \times K \) matrix \( \mathbf{Z} \)
Likelihood Function for GMM

Mixture density function is

\[ p(x) = \sum_z p(z) p(x | z) = \sum_{k=1}^{K} \pi_k N(x | \mu_k, \Sigma_k) \]

Since \( z \) has values \( \{z_k\} \) with probabilities \( \{\pi_k\} \)

Therefore Likelihood function is

\[ p(X | \pi, \mu, \Sigma) = \prod_{n=1}^{N} \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\} \]

Product is over the \( N \) i.i.d. samples

Therefore log-likelihood function is

\[ \ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\} \]

Which we wish to maximize

A more difficult problem than for a single Gaussian
Maximization of Log-Likelihood

\[
\ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\}
\]

- Goal is to estimate the three sets of parameters \( \pi_k, \mu_k, \Sigma_k \)
  - By taking derivatives in turn w.r.t each while keeping others constant
  - But there are no closed-form solutions
  - Task is not straightforward since summation appears in Gaussian and logarithm does not operate on Gaussian
- While a gradient-based optimization is possible, we consider the iterative EM algorithm

\( k = 1 \sum \pi_k N(x_n \mid \mu_k, \Sigma_k) \)
Some issues with GMM m.l.e.

• Before proceeding with the m.l.e. briefly mention two technical issues:
  1. Problem of singularities with Gaussian mixtures
  2. Problem of Identifiability of mixtures
Problem of Singularities with Gaussian mixtures

- Consider Gaussian mixture
  - components with covariance matrices \( \Sigma_k = \sigma_k^2 I \)
- Data point that falls on a mean \( \mu_j = \mathbf{x}_n \) will contribute to the likelihood function

\[
N(\mathbf{x}_n | \mathbf{x}_n, \sigma_j^2 I) = \frac{1}{(2\pi)^{1/2}} \frac{1}{\sigma_j} \quad \text{since } \exp(x_n - \mu_j)^2 = 1
\]

- As \( \sigma_j \to 0 \) term goes to infinity
- Therefore maximization of log-likelihood is not well-posed

\[
\ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(\mathbf{x}_n | \mu_k, \Sigma_k) \right\}
\]

  - Does not happen with a single Gaussian
    - Multiplicative factors go to zero
  - Does not happen in the Bayesian approach
- Problem is avoided using heuristics
  - Resetting mean or covariance
Problem of Identifiability

A density $p(x \mid \theta)$ is identifiable if $\theta \neq \theta'$ then there is an $x$ for which $p(x \mid \theta) \neq p(x \mid \theta')$

A $K$-component mixture will have a total of $K!$ equivalent solutions

- Corresponding to $K!$ ways of assigning $K$ sets of parameters to $K$ components
  - E.g., for $K=3$ $K! = 6$: 123, 132, 213, 231, 312, 321
  - For any given point in the space of parameter values there will be a further $K!-1$ additional points all giving exactly same distribution

- However any of the equivalent solutions is as good as the other

Two ways of labeling three Gaussian subclasses
EM for Gaussian Mixtures

- EM is a method for finding maximum likelihood solutions for models with latent variables.

- Begin with log-likelihood function

\[
\ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\}
\]

  - We wish to find \( \pi, \mu, \Sigma \) that maximize this quantity.
  - Task is not straightforward since summation appears in Gaussian and logarithm does not operate on Gaussian.

- Take derivatives in turn w.r.t

  - Means \( \mu_k \) and set to zero.
  - Covariance matrices \( \Sigma_k \) and set to zero.
  - Mixing coefficients \( \pi_k \) and set to zero.
EM for GMM: Derivative wrt $\mu_k$

- Begin with log-likelihood function
  \[
  \ln p(X \mid \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n \mid \mu_k, \Sigma_k) \right\}
  \]

- Take derivative w.r.t the means $\mu_k$ and set to zero
  - Making use of exponential form of Gaussian
  - Use formulas: \( \frac{d}{dx} \ln u = \frac{u'}{u} \) and \( \frac{d}{dx} e^u = e^u u' \)
  - We get

\[
0 = \sum_{n=1}^{N} \frac{\pi_k N(x_n \mid \mu_k, \Sigma_k)}{\sum_{j} \pi_j N(x_n \mid \mu_j, \Sigma_j)} \sum_{k}^{-1} (x_n - \mu_k)
\]

$\gamma(z_{nk})$ the posterior probabilities

Inverse of covariance matrix
M.L.E. solution for Means

• Multiplying by $\sum_k$ (assuming non-singularity)

$$\mu_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n$$

• Where we have defined

$$N_k = \sum_{n=1}^{N} \gamma(z_{nk})$$

– Which is the effective number of points assigned to cluster $k$

Mean of $k^{th}$ Gaussian component is the weighted mean of all the points in the data set:
where data point $x_n$ is weighted by the posterior probability that component $k$ was responsible for generating $x_n$
M.L.E. solution for Covariance

• Set derivative \[ \Sigma_k \] to zero
  – Making use of mle solution for covariance matrix of single Gaussian

\[
\Sigma_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk})(x_n - \mu_k)(x_n - \mu_k)^T
\]

– Similar to result for a single Gaussian for the data set but each data point weighted by the corresponding posterior probability
– Denominator is effective no of points in component
M.L.E. solution for Mixing Coefficients

- Maximize \( \ln p(X \mid \pi, \mu, \Sigma) \) w.r.t. \( \pi_k \)
  - Must take into account that mixing coefficients sum to one
  - Achieved using Lagrange multiplier and maximizing
    \[
    \ln p(X \mid \pi, \mu, \Sigma) + \lambda \left( \sum_{k=1}^{K} \pi_k - 1 \right)
    \]
  - Setting derivative wrt \( \pi_k \) to zero and solving gives
    \[
    \pi_k = \frac{N_k}{N}
    \]
Summary of m.l.e. expressions

- **GMM maximum likelihood parameter estimates**

Means

\[ \mu_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n \]

Covariance matrices

\[ \Sigma_k = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk})(x_n - \mu_k)(x_n - \mu_k)^T \]

Mixing Coefficients

\[ \pi_k = \frac{N_k}{N} \quad N_k = \sum_{n=1}^{N} \gamma(z_{nk}) \]

- All three are in terms of responsibilities
- and so we have not completely solved the problem
EM Formulation

• The results for $\mu_k, \Sigma_k, \pi_k$ are not closed form solutions for the parameters
  – Since $\gamma(z_{nk})$, the responsibilities depend on those parameters in a complex way

• Results suggest an iterative solution

• An instance of EM algorithm for the particular case of GMM
Informal EM for GMM

- First choose initial values for means, covariances and mixing coefficients
- Alternate between following two updates
  - Called E step and M step
- In E step use current value of parameters to evaluate posterior probabilities, or responsibilities
- In the M step use these posterior probabilities to re-estimate means, covariances and mixing coefficients
EM using Old Faithful

Data points and Initial mixture model

Initial E step Determine responsibilities

After first M step Re-evaluate Parameters

After 2 cycles

After 5 cycles

After 20 cycles
Comparison with $K$-Means

K-means result

E-M result

$L = 20$
Animation of EM for Old Faithful Data

**Code in R**

```r
#initial parameter estimates (chosen to be deliberately bad)
theta <- list( tau=c(0.5,0.5),
              mu1=c(2.8,75),
              mu2=c(3.6,58),
              sigma1=matrix(c(0.8,7,7,70),ncol=2),
              sigma2=matrix(c(0.8,7,7,70),ncol=2) )
```
Practical Issues with EM

- Takes many more iterations than $K$-means
  - Each cycle requires significantly more comparison
- Common to run $K$-means first in order to find suitable initialization
- Covariance matrices can be initialized to covariances of clusters found by $K$-means
- EM is not guaranteed to find global maximum of log likelihood function
Summary of EM for GMM

• Given a Gaussian mixture model
• Goal is to maximize the likelihood function w.r.t. the parameters (means, covariances and mixing coefficients)

Step1: Initialize the means $\mu_k$, covariances $\Sigma_k$, and mixing coefficients $\pi_k$, and evaluate initial value of log-likelihood
EM continued

- **Step 2: E step:** Evaluate responsibilities using current parameter values

\[
\gamma(z_k) = \frac{\pi_k N(x_n | \mu_k, \Sigma_k)}{\sum_{j=1}^{K} \pi_j N(x_n | \mu_j, \Sigma_j)}
\]

- **Step 3: M Step:** Re-estimate parameters using current responsibilities

\[
\mu_{k,\text{new}} = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) x_n
\]

\[
\Sigma_{k,\text{new}} = \frac{1}{N_k} \sum_{n=1}^{N} \gamma(z_{nk}) (x_n - \mu_{k,\text{new}})(x_n - \mu_{k,\text{new}})^T
\]

\[
\pi_{k,\text{new}} = \frac{N_k}{N}
\]

where \[N_k = \sum_{n=1}^{N} \gamma(z_{nk})\]
EM Continued

• **Step 4:** Evaluate the log likelihood

\[
\ln p(X | \pi, \mu, \Sigma) = \sum_{n=1}^{N} \ln \left\{ \sum_{k=1}^{K} \pi_k N(x_n | \mu_k, \Sigma_k) \right\}
\]

– And check for convergence of either parameters or log likelihood

• If convergence not satisfied return to Step 2
