

# Measurements and Data

Sargur Srihari

University at Buffalo  
The State University of New York

# Topics

- Types of Data
- Distance Measurement
- Data Transformation
- Forms of Data
- Data Quality

# Importance of Measurement

- Aim of mining structured data is to discover relationships that exist in the real world
  - business, physical, conceptual
- Instead of looking at real world we look at data describing it
- Data maps entities in the domain of interest to symbolic representation by means of a measurement procedure
- Numerical relationships between variables capture relationships between objects
- Measurement process is crucial

# Types of Measurement

- Ordinal,
  - e.g., excellent=5, very good=4, good=3...
- Nominal
  - e.g., color, religion, profession
  - Need non-metric methods
- Ratio
  - e.g., weight
  - has concatenation property, two weights add to balance a third:  $2+3 = 5$
  - changing scale (multiply by constant) does not change ratio
- Interval
  - e.g., temperature, calendar time
  - Unit of measurement is arbitrary, as well as origin

# Operational Measurement

- Measuring Programming Effort (Halstead 1977)

Programming effort  $e = am(n+m)\log(a+b)/2b$

$a$  = no of unique operators

$b$  = no of unique operands

$n$  = no of total operator occurrences

$m$  = no of operand occurrences

- Defines programming effort as well as a way of measuring it.
- Operational measurements are concerned with prediction whereas non-operational measurements are concerned with description

# Distance and Similarity

- Many data mining techniques are based on similarity measures between objects
  - nearest-neighbor classification
  - cluster analysis,
  - multi-dimensional scaling
- $s(i,j)$ : similarity,  $d(i,j)$ : dissimilarity
- Possible transformations:
  - $d(i,j) = 1 - s(i,j)$  or
  - $d(i,j) = \sqrt{2 * (1 - s(i,j))}$
- Proximity is a general term to indicate similarity and dissimilarity
- Distance is used to indicate dissimilarity

# Metric Properties

A metric is a dissimilarity (distance) measure that satisfies:

1.  $d(i,j) \geq 0$
2.  $d(i,j) = d(j,i)$
3.  $d(i,j) \leq d(i,k) + d(k,j)$

Commutativity

Triangle Inequality

# Examples of Metrics

- Euclidean Distance  $d_E$ 
  - Standardized (divide by variance)
  - Weighted  $d_{WE}$
- Minkowski measure
  - Manhattan Distance
- Mahanalobis Distance  $d_M$ 
  - Use of Covariance
- Binary data Distances

# Euclidean Distance between Vectors

$$d_E(x, y) = \left( \sum_{k=1}^p (x_k - y_k)^2 \right)^{1/2}$$

- Euclidean distance assumes variables are commensurate
  - E.g., each variable a measure of length
- If one were weight and other was length there is no obvious choice of units
- Altering units would change which variables are important

# Standardizing the Data

when variables are not commensurate

- Divide each variable by its standard deviation
  - Standard deviation for the  $k^{th}$  variable is

$$\sigma_k = \left( \frac{1}{n} \sum_{i=1}^n (x_k(i) - \mu_k)^2 \right)^{\frac{1}{2}}$$

where

$$\mu_k = \frac{1}{n} \sum_{i=1}^n x_k(i)$$

- Updated value that removes the effect of scale:

$$x_k' = \frac{x_k}{\sigma_k}$$

# Weighted Euclidean Distance

- If we know relative importance of variables

$$d_{WE}(i, j) = \left( \sum_{k=1}^p w_k ((x_k(i) - x_k(j))^2) \right)^{\frac{1}{2}}$$

# Use of Covariance in Distance

- Similarities between cup
- Suppose we measure cup-height 100 times and diameter only once
  - height will dominate although 99 of the height measurements are not contributing anything
- They are very highly correlated
- To eliminate redundancy we need a *data-driven method*
  - approach is to not only to standardize data in each direction but also to use covariance between variables

# Covariance between two Scalar Variables

$$\text{Cov}(x, y) = \frac{1}{n} \sum_{i=1}^n \left( x(i) - \bar{x} \right) \left( y(i) - \bar{y} \right)$$

Sample means

- A scalar value to measure how  $x$  and  $y$  vary together
- Obtained by
  - multiplying for each sample its mean-centered value of  $x$  with mean-centered value of  $y$
  - and then adding over all samples
- Large positive value
  - if large values of  $x$  tend to be associated with large values of  $y$  and small values of  $x$  with small values of  $y$
- Large negative value
  - if large values of  $x$  tend to be associated with small values of  $y$
- With  $d$  variables can construct a  $d \times d$  matrix of covariances
  - Such a covariance matrix is symmetric.

# For Vectors: Covariance Matrix and Data Matrix

- Let  $X = n \times d$  data matrix
- Rows of  $X$  are the data vectors  $x(i)$
- Definition of covariance:

$$Cov(i, j) = \frac{1}{n} \sum_{k=1}^n \left( x_k(i) - \bar{x} \right) \left( y_k(i) - \bar{y} \right)$$

- If values of  $X$  are mean-centered
  - i.e., value of each variable is relative to the sample mean of that variable
  - then  $V = X^T X$  is the  $d \times d$  covariance matrix

# Correlation Coefficient

Value of Covariance is dependent upon ranges of  $x$  and  $y$

Dependency is removed by

dividing values of  $x$  by their standard deviation  
and values of  $y$  by their standard deviation

$$\rho(X, Y) = \frac{\sum_{i=1}^n (x(i) - \bar{x})(y(i) - \bar{y})}{\sigma_x \sigma_y}$$

With  $p$  variables, can form a  $d \times d$  correlation matrix

# Correlation Matrix

Housing related variables

across city suburbs ( $d=11$ )

11 x 11 pixel image (White 1, Black -1)

Columns 12-14 have values -1,0,1 for pixel intensity reference

Remaining represent correlation matrix

Reference for -1, 0,+1

Variables 3 and 4 are highly negatively correlated with Variable 2

Variable 5 is positively correlated with Variable 11

Variables 8 and 9 are highly correlated

**Figure 2.1** A sample correlation matrix plotted as a pixel image. White corresponds to +1 and black to -1. The three rightmost columns contain values of -1, 0, and +1 (respectively) to provide a reference for pixel intensities. The remaining  $11 \times 11$  pixels represent the  $11 \times 11$  correlation matrix. The data come from a well-known data set in the regression research literature, in which each data vector is a suburb of Boston and each variable represents a certain general characteristic of a suburb. The variable names are (1) per-capita crime rate, (2) proportion of area zoned for large residential lots, (3) proportion of non-retail business acres, (4) nitric oxide concentration, (5) average number of rooms perdwelling, (6) proportion of pre-1940 homes, (7) distance to retail centers index, (8) accessibility to highways index, (9) property tax rate, (10) pupil-to-teacher ratio, and (11) median value of owner-occupied homes.

# Incorporating Covariance Matrix in Distance

Mahalanobis Distance between samples  $x(i)$  and  $x(j)$  is:

$$d_M(x(i), x(j)) = \underbrace{[(x(i) - x(j))^T]}_{1 \times d} \underbrace{\Sigma^{-1}}_{d \times d} \underbrace{(x(i) - x(j))]}_{d \times 1} \Bigg]^{\frac{1}{2}}$$

$T$  is transpose

$\Sigma$  is  $d \times d$  covariance matrix

$\Sigma^{-1}$  standardizes data relative to  $\Sigma$

Matrix multiplication  
yields a scalar value

$d_M$  discounts the effect of several highly correlated variables

# Generalizing Euclidean Distance

Minkowski or  $L_\lambda$  metric  $\left( \sum_{k=1}^p (x_k(i) - x_k(j))^\lambda \right)^{\frac{1}{\lambda}}$

- $\lambda = 2$  gives the Euclidean metric
- $\lambda = 1$  gives the Manhattan or City-block metric

$$\sum_{k=1}^p |x_k(i) - x_k(j)|$$

- $\lambda = \infty$  yields

$$\max_k |x_k(i) - x_k(j)|$$

Srihari

# Distance Measures for Binary Data

- Most obvious measure is *Hamming Distance* normalized by number of bits

$$\frac{S_{11} + S_{00}}{S_{11} + S_{10} + S_{01} + S_{00}}$$

Proportion of variables  
on which objects have same value

- If we don't care about irrelevant properties had by neither object we have *Jaccard Coefficient*

$$\frac{S_{11}}{S_{11} + S_{10} + S_{01}}$$

Example: two documents  
do not have certain terms

- *Dice Coefficient* extends this argument
  - If 00 matches are irrelevant then 10 and 01 matches should have half relevance
- Generalization to discrete values (non-binary)
  - Score 1 for if two objects agree and 0 otherwise
- Adaptation to mixed data types
  - Use additive distance measures

# Some Similarity/Dissimilarity Measures for N-dim Binary Vectors

Measure	$S(X, Y)$	$D(X, Y)$
Jaccard-Needham	$\frac{S_{11}}{S_{11} + S_{10} + S_{01}}$	$\frac{S_{10} + S_{01}}{S_{11} + S_{10} + S_{01}}$
Dice	$\frac{S_{11}}{2S_{11} + S_{10} + S_{01}}$	$\frac{S_{10} + S_{01}}{2S_{11} + S_{10} + S_{01}}$
Correlation	$\frac{S_{11} S_{00} - S_{10} S_{01}}{\sigma}$	$\frac{1}{2} - \frac{S_{11} S_{00} - S_{10} S_{01}}{2\sigma}$
Yule	$\frac{S_{11} S_{00} - S_{10} S_{01}}{S_{11} S_{00} + S_{10} S_{01}}$	$\frac{S_{10} S_{01}}{S_{11} S_{00} + S_{10} S_{01}}$
* Russell-Rao	$\frac{S_{11}}{N}$	$\frac{N - S_{11}}{N}$
* Sokal-Michener	$\frac{S_{11} + S_{00}}{N}$	$1 - \frac{S_{11} + S_{00}}{N}$
Rogers-Tanimoto	$\frac{S_{11} + S_{00}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$	$\frac{2S_{10} + 2S_{01}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$
* Rogers-Tanimoto-a	$\frac{S_{11} + S_{00}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$	$\frac{2(N - S_{11} - S_{00})}{2N - S_{11} - S_{00}}$
Kulzinsky	$\frac{S_{11}}{(S_{10} + S_{01})}$	$\frac{S_{10} + S_{01} - S_{11} + N}{(S_{10} + S_{01} + N)}$

where  $\sigma = ((S_{10} + S_{11})(S_{01} + S_{00})(S_{11} + S_{01})(S_{00} + S_{10}))^{1/2}$

$$S_{00}(X, Y) = \bar{X} \cdot \bar{Y}, S_{01}(X, Y) = \bar{X} \cdot Y, S_{10}(X, Y) = X \cdot \bar{Y}, S_{11}(X, Y) = X \cdot Y$$

Srihari

# Some Similarity/Dissimilarity Measures for N-dim Binary Vectors

Measure	$S(X, Y)$	$D(X, Y)$
Jaccard-Needham	$\frac{S_{11}}{S_{11} + S_{10} + S_{01}}$	$\frac{S_{10} + S_{01}}{S_{11} + S_{10} + S_{01}}$
Dice	$\frac{S_{11}}{2S_{11} + S_{10} + S_{01}}$	$\frac{S_{10} + S_{01}}{2S_{11} + S_{10} + S_{01}}$
Correlation	$\frac{S_{11}S_{00} - S_{10}S_{01}}{\sigma}$	$\frac{1}{2} - \frac{S_{11}S_{00} - S_{10}S_{01}}{2\sigma}$
Yule	$\frac{S_{11}S_{00} - S_{10}S_{01}}{S_{11}S_{00} + S_{10}S_{01}}$	$\frac{S_{10}S_{01}}{S_{11}S_{00} + S_{10}S_{01}}$
* Russell-Rao	$\frac{S_{11}}{N}$	$\frac{N - S_{11}}{N}$
* Sokal-Michener	$\frac{S_{11} + S_{00}}{N}$	$1 - \frac{S_{11} + S_{00}}{N}$
Rogers-Tanimoto	$\frac{S_{11} + S_{00}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$	$\frac{2S_{10} + 2S_{01}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$
* Rogers-Tanimoto-a	$\frac{S_{11} + S_{00}}{S_{11} + S_{00} + 2S_{10} + 2S_{01}}$	$\frac{2(N - S_{11} - S_{00})}{2N - S_{11} - S_{00}}$
Kulzinsky	$\frac{S_{11}}{(S_{10} + S_{01})}$	$\frac{S_{10} + S_{01} - S_{11} + N}{(S_{10} + S_{01} + N)}$

where  $\sigma = ((S_{10} + S_{11})(S_{01} + S_{00})(S_{11} + S_{01})(S_{00} + S_{10}))^{1/2}$

$S_{00}(X, Y) = \bar{X} \cdot \bar{Y}$ ,  $S_{01}(X, Y) = \bar{X} \cdot Y$ ,  $S_{10}(X, Y) = X \cdot \bar{Y}$ ,  $S_{11}(X, Y) = X \cdot Y$

Srihari

# Weighted Dissimilarity Measures for Binary Vectors

- Unequal importance to '0' matches and '1' matches
- Multiply  $S_{00}$  with  $\beta$  ( $[0,1]$ )
- Examples:

$$D^{sm}(X, Y) = 1 - \frac{S_{11} + \beta \cdot S_{00}}{N}$$

$$D^{rta}(X, Y) = \frac{2(N - S_{11} - \beta \cdot S_{00})}{2N - S_{11} - \beta \cdot S_{00}}$$

# Transforming the Data

Model depends on form of data

If  $Y$  is a function of  $X^2$  then we could use quadratic function or choose  $U = X^2$  and use a linear fit

$V_1$  is non-linearly Related to  $V_2$

Figure 2.2 A simple nonlinear relationship between variable  $V_1$  and subsequent figures  $V_1$  and  $V_2$  are on the  $X$  and  $Y$  axes respectively

$V_3=1/V_2$  is linearly related to  $V_1$

Figure 2.3 The data of figure 2.2 after the simple transformation of  $V_2$  to  $1/V_2$ .

Variance increases  
(regression assumes  
variance is constant)

Figure 2.4 Another simple nonlinear relationship. Here the variance of  $V_2$  as  $V_1$  increases.

Square root transformation  
keeps the variance constant

Srihari

25

Figure 2.5 The data of figure 2.4 after a simple square root transformation of  $V_2$ . Now the variance of  $V_2$  is relatively constant as  $V_1$  increases.

# Forms of Data

Standard Data (Data Matrix)

Multirelational Data

String

Event Sequence

Hierarchical Data

# Data Matrix

- Simplest form of data
- A set of  $d$  measurements on objects  $o(1) \dots o(n)$ 
  - $n$  rows and  $d$  columns
- Also called *standard data*, *data matrix* or *table*

# Multirelational Data (multiple data matrices)

Payroll Database

Name	Department	Age	Salary
	Name		

Department Table

Department	Budget	Manager
Name		

Can be combined together to form a data matrix with fields **name, department-name, age, salary, budget, manager**  
Or create as many rows as department-names  
Flattening requires needless replication (Storage issues)

# String Data

- Sequence of symbols from a finite alphabet
  - Standard matrix form is unsuitable
- Sequence of values from a categorical variable
  - Standard English text (alphanumeric characters, spaces, punctuation marks)
  - Protein and DNA/RNA sequences (A,C,G,T)

# Event Sequence Data

- Sequence of pairs of the form {event, occurrence time}
- A string where each sequence item is tagged with an occurrence time
  - Telecommunication alarm log
  - Transaction data (records of retail or financial)
  - Can occur asynchronously

# Data Quality

# Data Quality for Individual Measurements

- Data Mining Depends on Quality of data
- Many interesting patterns discovered may result from measurement inaccuracies.
- Sources of error
  - Errors in measurement
  - Carelessness
  - Instrumentation failure
  - Inadequate definition of what we are measuring

# Precision and Accuracy

- Precise Measurement
  - Small variability (measured by variance)
  - Repeated measurements yield same value
  - Many digits of precision is not necessarily accurate (results of calculations give many digits)
- Accurate
  - Not only small variability but close to true value
    - Precise measurement of height with shoes will not give an accurate measurement
    - Mean of repeated measurements and true value is “Bias”

# Data Quality for Collections of Data

- Collections of Data
  - Much of statistics is concerned with inference from a sample to a population
  - How to infer things from a fraction about entire population
  - Two sources of error:
    - sample size and bias

# Sample Size

- Confidence Intervals

# Biased Sample

- Inappropriate samples
  - To calculate average weight of people in New York it would be inappropriate to restrict samples to women, or to office workers
- Random sample is key to make valid inferences
  - Stratification (gender, age, education, occupation)
  - Proportional representation

# Anomalous Observations

**Figure 2.6** A plot of 200 points from highly positively correlated bivariate data (from a bivariate normal distribution), with a single easily identifiable outlier.
