NLP: N-Gram Models

Sargur N. Srihari
srihari@cedar.buffalo.edu

This is part of lecture slides on Deep Learning:
http://www.cedar.buffalo.edu/~srihari/CSE676
Topics in NLP

1. Overview
2. N-gram Models
3. Neural Language Models
4. High-dimensional Outputs
5. Combining Neural LMs with n-grams
6. Neural Machine Translation
7. Attention Models
8. Historical Perspective
Use of probability in NLP

• Some tasks involving probability

1. Predicting the next word

2. Which is more probable?

- all of a sudden I notice three guys standing on the sidewalk
- on guys all I of notice sidewalk three a sudden standing the

Probability essential in tasks with ambiguous input:

• Speech recognition
• Spelling correction, grammatical error correction
• Machine translation
Computing the probability of a word

• Consider task of computing $P(w \mid h)$
  – the probability of a word $w$ given some history $h$
  – Suppose the history $h$ is
    “its water is so transparent that”
  – We want the probability that the next word is the:
    $P(\text{the} \mid \text{its water is so transparent that})$
  – Estimate probability from frequency counts (C)
    $P(\text{the} \mid \text{its water is so transparent that}) = \frac{C(\text{its water is so transparent that the})}{C(\text{its water is so transparent that})}$

• Even the web is not big enough to estimate probability from frequency counts
A better method for probabilities

• Chain rule of probability

\[ P(X_1..X_n) = P(X_1)P(X_2|X_1)P(X_3|X_1^2) \ldots P(X_n|X_1^{n-1}) = \prod_{k=1}^{n} P(X_k|X_1^{k-1}) \]

– Applying it to words

\[ P(w^n_1) = P(w_1)P(w_2|w_1)P(w_3|w_2^2) \ldots P(w_n|w^{n-1}_1) = \prod_{k=1}^{n} P(w_k|w^{k-1}_1) \]

• shows link between computing joint probability of a sequence and computing the conditional probability of a word given previous words.

• The intuition of the n-gram model is that instead of computing the probability of a word given its entire history, we can approximate the history by just the last few words.
Bigram Probabilities

- **Bigram**
  - instead of computing the probability
    \[ P(\text{the}|\text{Walden Pond’s water is so transparent that}) \]
  - we approximate it with the probability
    \[ P(\text{the}|\text{that}) \]

- **We are making the assumption that**
  - \[ P(w_n|w_{n-1}) = P(w_n|w_{n-1}) \]
N-Gram Models

- An $n$-gram is a sequence of tokens, e.g., words
  - $n$-gram models define the conditional probability of the $n^{th}$ token given the previous $n-1$ tokens

- Products of conditional distributions define probability distributions of longer sequences

$$P(x_1, \ldots, x_\tau) = P(x_1, \ldots, x_{n-1}) \prod_{t=n}^{\tau} P(x_t \mid x_{t-n+1}, \ldots, x_{t-1})$$

  - Comes from chain rule of probability
    - $P(x_1, \ldots, x_n) = P(x_n \mid x_1, \ldots, x_{n-1}) P(x_1, \ldots, x_{n-1})$

- Distribution of $P(x_1, \ldots, x_{n-1})$ may be defined by a different model with a smaller value of $n$
Common $n$-grams

- Count how many times each possible $n$-gram occurs in the training set
  - Models based on $n$-grams have been core building block of NLP
- For small values of $n$, we have
  - $n=1$ : unigram $P(x_1)$
  - $n=2$ : bigram $P(x_1, x_2)$
  - $n=3$ : trigram $P(x_1, x_2, x_3)$
Examples of n-grams

1. Frequencies of 4 and 3-grams

2. Protein Sequencing
3. DNA Sequencing
4. Computational linguistics (character)
5. Computational Linguistics (word)

#### Bigram Probabilities

\[
P(<s> \text{ i want english food } </s>) = P(i|<s>)P(\text{want}|i)P(\text{english}|\text{want})P(\text{food}|\text{english})P(<s>|\text{food})
\]

\[
= .25 \times .33 \times .0011 \times 0.5 \times 0.68
\]

\[
= .000031
\]
Training \( n \)-Gram Models

- Usually train both an \( n \)-gram model and an \( n-1 \)-gram model making it easy to compute

\[
P(x_t \mid x_{t-n+1}, \ldots, x_{t-1}) = \frac{P_n(x_{t-n+1}, \ldots, x_t)}{P_{n-1}(x_{t-n+1}, \ldots, x_{t-1})}
\]

- Simply by looking up two stored probabilities
- For this to exactly reproduce inference in \( P_n \) we must omit the final character from each sequence when we train \( P_{n-1} \)
Example of Trigram Model Computation

• How to compute probability of “THE DOG RAN AWAY”
  • The first words of the sentence cannot be handled by the default formula on conditional probability because there is no context at the beginning of the sentence
  • Instead we must use the marginal probability over words at the start of the sentence. We thus evaluate $P_3$(THE DOG RAN)
  • The last word may be predicted using the typical case, of using conditional distribution $P$(AWAY|DOG RAN)
  • Putting this together

$$P(\text{THE DOG RAN AWAY}) = \frac{P_3(\text{THE DOG RAN})P_3(\text{DOG RAN AWAY})}{P_2(\text{DOG RAN})}$$
Limitation of Maximum Likelihood for $n$-gram models

- $P_n$ estimated from training samples is very likely to be zero in many cases even though the tuple $x_{t-n+1}, \ldots, x_t$ may appear in test set
  - When $P_{n-1}$ is zero the ratio is undefined
  - When $P_{n-1}$ is non-zero but $P_n$ is zero the log-likelihood is $-\infty$

- To avoid such catastrophic outcomes, $n$-gram models employ smoothing
  - Shift probability mass of observed tuples to unobserved similar ones
Smoothing techniques

1. Add non-zero mass to next symbol values
   • Justified as Bayesian inference with a uniform or Dirichlet prior over count parameters

2. Mixture of higher/lower-order $n$-gram models
   • with higher-order models providing more capacity and lower-order models more likely to avoid counts of zero

3. Back-off methods look-up lower-order $n$-grams if frequency of context $x_{t-1}, \ldots, x_{t-n+1}$ is too small to use higher-order model
   • More formally, they estimate distribution over $x_t$ by using contexts $x_{t-n+k}, \ldots, x_{t-1}$, for increasing $k$, until a sufficiently reliable estimate is found
$N$-gram with Backoff

• For high order models, e.g, $N=5$, only a small fraction of $N$-grams appear in training corpus
  – a problem of data sparsity
    • with 0 probability for almost all sentences
• To counteract this, several back-off techniques have been suggested, the most popular being:

\[
P_N^{NG}(w_t) = \begin{cases} 
  p_{w_t,c_{N-1}} & \text{if not zero} \\
  P_{N-1}^{NG}(w_t)\alpha c_{N-1} & \text{otherwise}
\end{cases}
\]

– where $\alpha$ and $p$ are called back-off coefficients and discounted probabilities, respectively

Shortcomings of $n$-gram models

- Vulnerable to curse of dimensionality
- There are $|V|^n$ possible $n$-grams and $|V|$ is large
- Even with a massive training set most $n$-grams will not occur
- One way to view a classical $n$-gram model is that it is performing nearest-neighbor lookup
  - In other words, it can be viewed as a local non-parametric predictor, similar to $k$-nearest neighbors
  - Any two words are at same distance from each other
Class-based language models

• To improve statistical efficiency of $n$-gram models
  – Introduce notion of word categories
    • Share statistics of words in same categories
• Idea: use a clustering algorithm to partition words into clusters based on their co-occurrence frequencies with other words
  – Model can then use word-class IDs rather than individual word-IDs to represent context
• Still much information is lost in this process
