Topics in NLP

1. Overview
2. N-gram Models
3. Neural Language Models
4. High-dimensional Outputs
5. Combining Neural Language Models with n-grams
6. Neural Machine Translation
7. Historical Perspective
Computing the probability of a word

• Consider task of computing $P(w|h)$
  – the probability of a word $w$ given some history $h$
  – Suppose the history $h$ is
    “its water is so transparent that”
  – We want the probability that the next word is the:
    $P(\text{the}|\text{its water is so transparent that})$
  – Estimate probability from frequency counts ($C$)
    $P(\text{the}|\text{its water is so transparent that}) = \frac{C(\text{its water is so transparent that the})}{C(\text{its water is so transparent that})}$

• Even the web is not big enough to estimate probability from frequency counts
A better method for probabilities

- **Chain rule of probability**
  \[ P(X_1.. X_n) = P(X_1)P(X_2|X_1)P(X_3|X_1^2) \ldots P(X_n|X_1^{n-1}) = \prod_{k=1}^{n} P(X_k|X_1^{k-1}) \]
  - Applying it to words
  \[ P(w^n_1) = P(w_1)P(w_2|w_1)P(w_3|w^2_1)\ldots P(w_n|w^{n-1}_1) = \prod_{k=1}^{n} P(w_k|w^{k-1}_1) \]
  - shows link between computing joint probability of a sequence and computing the conditional probability of a word given previous words.

- **The intuition of the n-gram model** is that instead of computing the probability of a word given its entire history, we can approximate the history by just the last few words.
Bigram Probabilities

• **Bigram**
  – instead of computing the probability
    \[ P(\text{the}|\text{Walden Pond’s water is so transparent that}) \]
  – we approximate it with the probability
    \[ P(\text{the}|\text{that}) \]

• **We are making the assumption that**
  – \[ P(w_n|w^{n-1}_1) = P(w_n|w_{n-1}) \]
N-Gram Models

- An \( n \)-gram is a sequence of tokens, e.g., words
  - \( n \)-gram models define the conditional probability of the \( n^{th} \) token given the previous \( n-1 \) tokens

- Products of conditional distributions define probability distributions of longer sequences

\[
P(x_1, \ldots, x_\tau) = P(x_1, \ldots, x_{n-1}) \prod_{t=n}^{\tau} P(x_t | x_{t-n+1}, \ldots, x_{\tau-1})
\]

- Comes from chain rule of probability

\[
P(x_1, \ldots, x_n) = P(x_n | x_{1}, \ldots, x_{n-1}) P(x_1, \ldots, x_{n-1})
\]

- Distribution of \( P(x_1, \ldots, x_{n-1}) \) may be defined by a different model with a smaller value of \( n \)
Common $n$-grams

• Count how many times each possible $n$-gram occurs in the training set
  – Models based on $n$-grams have been core building block of NLP

• For small values of $n$, we have

  $n=1$ : unigram $P(x_1)$
  $n=2$ : bigram $P(x_1, x_2)$
  $n=3$ : trigram $P(x_1, x_2, x_3)$
Examples of n-grams

1. Frequencies of 4 and 3-grams

2. Protein Sequencing
3. DNA Sequencing
4. Computational linguistics (character)
5. Computational Linguistics (word)
Unigram and Bigram Probabilities

**Unigram Counts**

<table>
<thead>
<tr>
<th>i</th>
<th>want</th>
<th>to</th>
<th>eat</th>
<th>chinese</th>
<th>food</th>
<th>lunch</th>
<th>spend</th>
</tr>
</thead>
<tbody>
<tr>
<td>2533</td>
<td>927</td>
<td>2417</td>
<td>746</td>
<td>158</td>
<td>1093</td>
<td>341</td>
<td>278</td>
</tr>
</tbody>
</table>

**Bigram Counts**

<table>
<thead>
<tr>
<th>i</th>
<th>want</th>
<th>608</th>
<th>686</th>
<th>16</th>
<th>2</th>
<th>82</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
<td>4</td>
<td>2</td>
<td>16</td>
<td>2</td>
<td>82</td>
<td>10</td>
</tr>
</tbody>
</table>

**Bigram Probabilities**

\[
P(<s> \text{ i want english food } </s>)
\]

\[
= P(i|<s>)P(\text{want}|i)P(\text{english}|\text{want})
\]

\[
P(\text{food}|\text{english})P(</s>|\text{food})
\]

\[
= .25 \times .33 \times .0011 \times 0.5 \times 0.68
\]

\[
= .000031
\]
Training $n$-Gram Models

- Usually train both an $n$-gram model and an $n-1$-gram model making it easy to compute

\[
P(x_t \mid x_{t-n+1}, \ldots, x_{t-1}) = \frac{P_n(x_{t-n+1}, \ldots, x_t)}{P_{n-1}(x_{t-n+1}, \ldots, x_{t-1})}
\]

- Simply by looking up two stored probabilities
- For this to exactly reproduce inference in $P_n$ we must omit the final character from each sequence when we train $P_{n-1}$
Example of Trigram Model Computation

**How to compute probability of** “THE DOG RAN AWAY”

- The first words of the sentence cannot be handled by the default formula on conditional probability because there is no context at the beginning of the sentence.
- Instead, we must use the marginal probability over words at the start of the sentence. We thus evaluate $P_3(\text{THE DOG RAN})$.
- The last word may be predicted using the typical case, of using conditional distribution $P(\text{AWAY} | \text{DOG RAN})$.
- Putting this together,

$$P(\text{THE DOG RAN AWAY}) = \frac{P_3(\text{THE DOG RAN})P_3(\text{DOG RAN AWAY})}{P_2(\text{DOG RAN})}$$
Limitation of Maximum Likelihood for $n$-gram models

- $P_n$ estimated from training samples is very likely to be zero in many cases even though the tuple $x_{t-n+1}, \ldots, x_t$ may appear in test set
  - When $P_{n-1}$ is zero the ratio is undefined
  - When $P_{n-1}$ is non-zero but $P_n$ is zero the log-likelihood is $-\infty$

- To avoid such catastrophic outcomes, $n$-gram models employ smoothing
  - Shift probability mass of observed tuples to unobserved similar ones
Smoothing techniques

1. Add non-zero mass to next symbol values
   • Justified as Bayesian inference with a uniform or Dirichlet prior over count parameters

2. Mixture of higher/lower-order $n$-gram models
   • with higher-order models providing more capacity and lower-order models more likely to avoid counts of zero

3. Back-off methods look-up lower-order $n$-grams if frequency of context $x_{t-1}, \ldots, x_{t-n+1}$ is too small to use higher-order model
   • More formally, they estimate distribution over $x_t$ by using contexts $x_{t-n+k}, \ldots, x_{t-1}$, for increasing $k$, until a sufficiently reliable estimate is found
Shortcomings of $n$-gram models

- Vulnerable to curse of dimensionality
- There are $|V|^n$ possible $n$-grams and $|V|$ is large
- Even with a massive training set most $n$-grams will not occur
- One way to view a classical $n$-gram model is that it is performing nearest-neighbor lookup.
  - In other words, it can be viewed as a local non-parametric predictor, similar to k-nearest neighbors
  - Any two words are at same distance from each other
Class-based language models

• To improve statistical efficiency of $n$-gram models
  – Introduce notion of word categories
    • Share statistics of words in same categories
• Idea: use a clustering algorithm to partition words into clusters based on their co-occurrence frequencies with other words
  – Model can then use word-class IDs rather than individual word-IDs to represent context
• Still much information is lost in this process
