Attention Models

Sargur N. Srihari
srihari@buffalo.edu

This is part of lecture slides on Deep Learning:
http://www.cedar.buffalo.edu/~srihari/CSE676
Topics in NLP

1. N-gram Models
2. Neural Language Models
3. High-Dimensional Outputs
4. Combining Neural Language Models with n-grams
5. Neural Machine Translation
6. Attention Models
7. Historical Perspective
Topics in Attention Models

• Importance of Attention Models
1. RNN-based Encoder-Decoder
2. Encoder-Decoder with Attention
3. Transformer model of Attention
   – Self-Attention
4. Generative pre-training of Transformer Network
5. BERT: Bidirectional Encoder Representations from Transformers

• References
What is Attention?

• How we correlate words in one sentence

She is eating a green apple.

– When we see “eating”, we expect a food word soon
  • “Green” describes food, but much with “eating” directly

• Attention in deep learning is a vector of importance weights

  – in order to predict or infer a word in a sentence, we estimate using the attention vector how strongly it is correlated with (or “attends to”) other elements

Importance of Attention Models

- Attention Model (AM) was first introduced for Machine Translation [Bahdanau et al., 2014]
- Now, widely used in neural networks for
  - NLP
  - Statistical Learning
  - Speech
  - Computer Vision
Reasons for AM Advancement

1. AM models are state-of-the-art for tasks of
   – Machine Translation, Question Answering, Sentiment Analysis, Part-of-Speech tagging, Constituency Parsing and Dialogue Systems

2. Advantages beyond improving performance
   – Improving interpretability of neural networks, which are otherwise black-box models

3. Overcome challenges with RNNs
   – Performance with increase in length of input
Intuition behind Attention Models

• **Visual processing system**
  – Pay visual attention to different regions of image
    • Focus selectively on parts of image, while ignoring irrelevant information to assist in perception

• **In translation and summarization tasks**
  – Only certain words in the input sequence may be relevant for predicting the next word

• **Image captioning problem**
  – Some regions of the input image may be more relevant for generating the next word in the caption
AM in Sentiment Analysis

1. pork belly= delicious.
2. scallops?
3. I don't even like scallops, and these were a-m-a-z-i-n-g
4. fun and tasty cocktails
5. next time I in Phoenix, I will go back here .
• Highly recommend.

AM learns that out of five sentences, first and third sentences are more relevant
Furthermore, the words delicious and amazing within those sentences are more meaningful to determine the sentiment of the review
Types of Attention Models

1. Basic encoder-decoder RNN model
2. Encoder-decoder with Attention
3. Transformer model with no recurrence
4. Generative pre-training of Attention model
5. BERT with no decoder, using bidirectionality
An **encoder** processes the input sequence and compresses the information into a context vector (also known as sentence embedding or “thought” vector) of a **fixed length**.

This representation is expected to be a good summary of the meaning of the whole source sequence.

A **decoder** is initialized with the context vector to emit the transformed output. Both the encoder and decoder are recurrent neural networks, i.e. using **LSTM or GRU** units.
Sequence-to-sequence RNN model

– A traditional encoder-decoder architecture based on RNNs

• Encoder RNN encodes input sequence of tokens \( \{x_1, x_2 \ldots x_T\} \) into fixed length vectors \( \{h_1^e, h_2^e \ldots h_T^e\} \)

• Decoder RNN takes single fixed length vector \( h_T^e \) as input and generates output sequence \( \{y_1, y_2 \ldots y_{T'}\} \), token by token, where \( T' \) is length of output sequence

• At each position \( t \), \( h_t^e \) and \( h_t^d \) denote the hidden states of the encoder and decoder respectively
Basic RNN-based Encoder-Decoder

- Final hidden state of the encoder RNN serves as context for the decoder in its role as $h_0$ in the decoder RNN

Source: Jurafsky and Martin, Speech and Language Processing, 2020
Encoder/decoder using GRU/LSTM cells

• To handle arbitrary input and output lengths:
  – Basic RNN cell changed to GRU or LSTM cell
  – tanh replaced by ReLU

• Main deficit left unsolved:
  – Is one hidden state really enough?
Summary of Encoder-Decoder

- Encoder & decoder have the same structure (RNN)
- Final encoder state is only context for decoder
  - Available to decoder as its initial hidden state
- Encoder-decoder has three components
  1. Encoder accepts input sequence, $x_1^n$, and generates a sequence of contextualized representations $h_1^n$
  2. A context vector, $c$, which is a function of $h_1^n$, and conveys the essence of the input to the decoder
  3. A decoder, which accepts $c$ as input and generates an arbitrary length sequence of hidden states $h_1^m$, from which a corresponding sequence of output states $y_1^m$, can be obtained
**Abstracted Encoder-Decoder**

**Encoder**

Simple RNNs, LSTMs, GRUs, CNNs, transformer networks

Only a single network layer is shown for the encoder, however, stacked architectures are the norm, where the output states from the top layer of the stack are taken as the final representation.

A widely used encoder design makes use of stacked Bi-LSTMs

**Decoder**

Autoregressive generation is used to produce an output sequence, an element at a time, until an end-of-sequence marker is generated.

This incremental process is guided by the context provided by the encoder as well as any items generated for earlier states by the decoder.

Again, a typical approach is to use an LSTM or GRU-based RNN

Source: Jurafsky and Martin, Speech and Language Processing, 2020
Challenges of traditional encoder-decoder

1. Encoder compresses all input information into a single fixed length vector $h_T$ that is passed to the decoder
   - Using a single fixed length vector to compress long input sequences leads to loss of information

2. It is unable to model alignment between input and output sequences
   - Which is essential for structured output tasks such as translation or summarization
Intuition of what is needed

• In sequence-to-sequence tasks, each output token is expected to be more influenced by some specific parts of the input sequence.

• However, decoder lacks any mechanism to selectively focus on relevant input tokens while generating each output token.
Types of Attention Models

1. Basic encoder-decoder RNN model
2. Encoder-decoder with Attention
3. Transformer model with no recurrence
4. Generative pre-training of Attention model
5. BERT with no decoder, using bidirectionality
Attention Mechanism

• To overcome deficiencies of simple approaches to context, we need
  1. A mechanism that can take the entire encoder context into account
  2. That dynamically updates during the course of decoding, and that can be embodied in a fixed-size vector

• Taken together, we’ll refer such an approach as an attention mechanism
Key idea of Attention Model

• AM aims at mitigating these challenges by allowing the decoder to access the entire encoded input sequence \( \{h_1, h_2 \ldots h_T\} \)

• The central idea is to induce attention weights over the input sequence to prioritize the set of positions where relevant information is present for generating the next output token
Encoder-Decoder with Attention

Computing decoder hidden state \( h^d_i \) is based on previous hidden state \( h^d_{i-1} \), previous word generated \( y_{i-1} \), and current context vector \( c_i \):

\[
h^d_i = g(\hat{y}_{i-1}, h^d_{i-1}, c_i)
\]

Context vector \( c_i \) obtained by comparing the previous hidden state \( h^d_{i-1} \) to all of the encoder hidden states \( h^e_j \):

Score is a measure of similarity of the decoder hidden state to each encoder hidden state

Some alignment score functions

Neural network determines attention weights \( \alpha_{ij} \):

\[
\alpha_{ij} = \text{softmax}(\text{score}(h^d_{i-1}, h^e_j)) \quad \forall j \in e
\]

\[
c_i = \sum_j \alpha_{ij} h^e_j
\]

\( c_i \): Context vector for output \( y_i \)

\( \alpha_{ij} \): How well two words \( y_i \) and \( x_j \) are aligned

Score function examples:

\[
\text{score}(h^d_{i-1}, h^e_j) = h^d_{i-1} \cdot h^e_j
\]

\[
\text{score}(h^d_{i-1}, h^e_j) = h^d_{i-1} W_s h^e_j
\]

Self-Attention

- **Self-attention**, also known as **intra-attention**
  - is an attention mechanism relating different positions of a single sequence in order to compute a representation of the same sequence
  - Useful in machine reading, text summarization, image description generation

- **Broad categories of Attention:**

<table>

Neural network for learning $\alpha_{ij}$

- Attention module learns weights $\alpha_{ij}$
  - which capture relevance between
    - $h_i^d$ (decoder hidden state, or query state)
    - $h_j^e$ (encoder hidden state, or candidate state)

- Attention weights are then used to build a context vector $c_i$,
  - At each decoding position $i$,
    - context vector $c_i$ is a weighted sum of encoder hidden states and attention weights
      \[ c_i = \sum_j \alpha_{ij} h_j^e \]

- Context vectors $c$ are used to determine next decoder hidden states
  \[ h_i^d = g(\hat{y}_{i-1}, h_{i-1}^d, c_i) \]

This context vector is the mechanism by which decoder can access the entire input sequence and also focus on the relevant positions in the input sequence.
An Attention Architecture

Similar to basic encoder-decoder. But plug a context vector into gap between encoder and decoder.

\[
\alpha_{ts} = \frac{\exp \left( \text{score}(h_t, \tilde{h}_s) \right)}{\sum_{s'=1}^{S} \exp \left( \text{score}(h_{t}, \tilde{h}_{s'}) \right)} \quad \text{[Attention weights]} \quad (1)
\]

\[
c_t = \sum_s \alpha_{ts} \tilde{h}_s \quad \text{[Context vector]} \quad (2)
\]

\[
a_t = f(c_t, h_t) = \tanh(W_c[ci; hi]) \quad \text{[Attention vector]} \quad (3)
\]

https://medium.com/syncedreview/a-brief-overview-of-attention-mechanism-13c578ba9129
Types of Attention Models

1. Basic encoder-decoder RNN model
2. Encoder-decoder with Attention
3. Transformer model with no recurrence
4. Generative pre-training of Attention model
5. BERT with no decoder, using bidirectionality
Transformer AM with no recurrence

- Transformer is an attention mechanism to learn contextual relations between words
  - It includes two mechanisms
    1. An Encoder that reads text input
    2. A Decoder that produces a prediction for the task

- Model has no recurrence
  - Self-attention to represent input/output without RNN

- Allows more parallelism
  - High translation quality: state-of-the-art
    - Training 12 hours on eight P100 GPUs
The Transformer Model

- Has an encoder-decoder architecture
  - Encoder maps input \((x_1, \ldots, x_n)\) to representations \(z = (z_1, \ldots, z_n)\)
  - Given \(z\), decoder generates \((y_1, \ldots, y_m)\) element-wise

- At each step model is autoregressive
  - i.e., consumes previously generated symbols as additional input when generating the next
Encoder and Decoder use Attention

Encoder & decoder are:
1. stacked (See next slide)
2. self-attention
3. point-wise,
4. fully connected layers

Stacked Encoder, Decoder

INPUT: Je suis étudiant

OUTPUT: I am a student
Self-Attention

• Input sentence to translate:
  • Second Law of Robotics: A robot must obey the orders given it by human beings except where such orders would conflict with the First Law.
    – Highlighted words refer to other words
      – it refers to the robot, such orders refers to the earlier part of the law, namely “the orders given it by human beings”, The First Law refers to the entire First Law

• This is what self-attention does
  – It bakes-in the model’s understanding of relevant and associated words that explain the context of a certain word before processing that word
  – By assigning scores to how relevant each word in the segment is, and adding up their vector representation
Self-Attention Process

This self-attention layer is paying attention to “a robot” when it processes the word “it”. The vector it will pass to its neural network is a sum of the vectors for each of the three words multiplied by their scores.

Self-attention is processed along the path of each token in the segment.
The significant components are three vectors: Query, Key and Value
Transformer Encoder Detail

- A stack of $N_x = 6$ identical layers
- Each layer has two sub-layers:
  1. A multi-head self-attention mechanism
  2. A position-wise fully connected feed-forward network
     A residual connection around each of the two sub-layers, followed by layer normalization
- Layer normalization: normalization statistics from the summed inputs to the neurons within a hidden layer

Output of each sub-layer is $\text{LayerNorm}(x + \text{Sublayer}(x))$, where $\text{Sublayer}(x)$ is the function implemented by the sub-layer itself.

Residual connections, sub-layers, embedding layers produce outputs of dimension $d_{\text{model}} = 512$
Transformer Decoder Detail

Decoder is also a stack of $N_x = 6$ identical layers. Has a third sub-layer which performs multi-head attention over the output of the encoder stack. Residual connections around each of the two sub-layers, followed by layer normalization.

Self-attention sub-layer in the decoder stack is modified to prevent positions from attending to subsequent positions. This masking, and by off-setting output embeddings by one position, predictions for at $i$ depend only on known outputs at positions $< i$.

\[
\text{Attention}(Q, K, V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V
\]
Query, Key and Value in QA

- **Key-Value Memory Networks for Question Answering**
  - **Example**
    - Blade Runner directed-by Ridley Scott has the form \textit{subject-relation-object}
    - \textit{Key} is composed of \textit{subject} (Blade Runner) and \textit{relation} (directed by)
    - \textit{Value} is the \textit{object} (Ridley Scott)
    - \textit{Query} is Who directed Blade Runner?

The input consists of queries and keys of dimension $d_k$, and values of dimension $d_k$. We compute the dot products of the query with all keys, divide each by $\sqrt{d_k}$, and apply a softmax function to obtain the weights on the values.

We compute the attention function on a set of queries simultaneously, packed together into a matrix $Q$. The keys and values are also packed together into matrices $K$ and $V$. We compute the matrix of outputs as:

$$\text{Attention}(Q, K, V) = \text{softmax}(\frac{QK^T}{\sqrt{d_k}})V$$
Detail of Multi-head attention

- Several attention layers run in parallel

Outputs are concatenated and linearly transformed into the expected dimensions. Allows model to jointly attend to information from different representation subspaces at different positions.

\[ \text{MultiHead}(Q, K, V) = \text{Concat}(\text{head}_1, \ldots, \text{head}_h) \]

where \( \text{head}_i = \text{Attention}(QW^Q_i, KW^K_i; VW^V_i) \)

\( W^Q_i \in \mathbb{R}^{d_{\text{model}} \times d_k}, W^K_i \in \mathbb{R}^{d_{\text{model}} \times d_k} \) and \( W^V_i \in \mathbb{R}^{d_{\text{model}} \times d_v} \)
Types of Attention Models

1. Basic encoder-decoder RNN model
2. Encoder-decoder with Attention
3. Transformer model with no recurrence
4. Generative pre-training of Attention model
5. BERT with no decoder, using bidirectionality
Improvements of Transformer

1. Generative Pre-training (GPT)
   - Described next
   - Has achieved new state-of-the art for the following tasks:
     • Textual entailment, semantic similarity, reading comprehension, common sense reasoning, linguistic acceptability, multi-task benchmark

2. BERT
   - BERT is an improvement of GPT
Generative Pre-training (GPT)

- **OpenAI multilayer decoder**
  
  \[ W_e \text{ is the token embedding matrix} \]
  
  \[ W_p \text{ is the position embedding matrix} \]
  
  \[ h_0 = UW_e + W_p \]
  
  \[ h_i = \text{transformer block} \left( h_{i-1} \right) \forall i \in [1, n] \]

- **Unsupervised pretraining task**
  - **Language Modeling**

- **Supervised fine-tuning**
  - **Multitask learning**

Language Modeling Loss

\[ P(u) = \text{softmax} (h_n W_e^T) \]

\[ L_1(U) = \sum_i \log P(u_i | u_{i-k}, ..., u_{i-1}; \Theta) \]

Classification Loss

\[ P(y|x^1, ..., x^m) = \text{softmax}(h_n^m W_y) \]

\[ L_2(c) = \sum_{(x,y)} \log P(y|x^1, ..., x^m) \]

Final Loss

\[ L_3(c) = L_2(c) + \lambda \ast L_1(c) \]

Types of Attention Models

1. Basic encoder-decoder RNN model
2. Encoder-decoder with Attention
3. Transformer model with no recurrence
4. Generative pre-training of Attention model
5. BERT with no decoder, using bidirectionality
BERT
(Bidirectional Encoder Representations from Transformers)

1. Uses Transformer attention mechanism to learn contextual relations between words
   – Transformer includes two mechanisms
     1. An Encoder that reads text input
     2. A Decoder that produces a prediction for the task
   – Since BERT’s goal is to generate a language model, only the encoder mechanism is necessary

2. Uses Bidirectional training
   – Deeper sense of context/flow than single-direction
     • Masked LM (MLM) allows bidirectional training
Comparison of BERT and GPT

• BERT is an improvement on GPT

• The main differences are:
  – Bidirectional training
  – Different pre-training tasks (masked language model and next sentence prediction)
  – Trained on a much bigger corpus (BookCorpus (800M words) + Wikipedia (2500M words))
  – 3 x as many parameters for the large version
  – Pre-trained model for 102 languages
Bidirectionality

Arrows indicate information flow from one layer to next
Green boxes at top indicate final contextualized representation of each input word
Evident from the above image:
- BERT is bi-directional
- GPT is unidirectional (information flows from left-to-right)
- ELMo is shallowly bidirectional
Text Pre-processing

Position Embeddings:
BERT learns and uses positional embeddings to express the position of words in a sentence. These are added to overcome the limitation of Transformer which, unlike an RNN, is not able to capture “sequence” or “order” information.

Segment Embeddings:
BERT can also take sentence pairs as inputs for tasks (Question-Answering). That’s why it learns a unique embedding for the first and the second sentences to help the model distinguish between them. In the above example, all the tokens marked as EA belong to sentence A (and similarly for EB).

Token Embeddings:
These are the embeddings learned for the specific token from the WordPiece token vocabulary.
Pre-training BERT

• BERT is pre-trained on two NLP tasks:
  1. Masked Language Modeling (For Bidirectionality)
  2. Next Sentence Prediction
Masked Language Model

- Before feeding word sequences 15% of words in each sequence replaced with a [MASK] token
- Model attempts to predict original value of masked words, based on context provided by non-masked words in sequence
- Prediction of the output words requires
  - Adding a classifier layer on top of encoder output
  - Multiplying output vectors by the embedding matrix, transforming them into the vocabulary dimension.
  - Calculating probability of each word in the vocabulary with softmax.
Word prediction using masking

Alaska is about twelve times larger than New York
Alaska is about twelve times larger than New York
Alaska is about twelve times larger than New York
Alaska is about twelve times larger than New York
Alaska is about twelve times larger than New York
Next Sentence Prediction

• A text dataset of 100,000 sentences has 50,000 training examples or pairs of sentences as training data.
  – For 50% of pairs, the second sentence would be the next sentence to the first sentence
  – For the remaining 50% of pairs, second sentence would be a random sentence from corpus

  • The labels for the first case would be ‘IsNext’ and ‘NotNext’ for the second case
BERT Architecture

• BERT architecture builds on top of Transformer

• There are two variants:
  – BERT Base:
    • 12 layers (transformer blocks), 12 attention heads, and 110 million parameters
  – BERT Large:
    • 24 layers (transformer blocks), 16 attention heads and, 340 million parameters
