Generative Adversarial Networks: Theory

Sargur N. Srihari
srihari@cedar.buffalo.edu
Topics in GAN Theory

1. Generator and Discriminator Networks
2. Interaction between $G$ and $D$
3. Value Function
4. SGD for GAN
Generator and Discriminator Networks

1. Generator Network directly produces samples
   \[ x = G(z; \theta^{(g)}) \]

2. Discriminator Network, its adversary, attempts to distinguish samples drawn from training data and samples drawn from generator
   - Discriminator emits a probability value
     \[ D(x; \theta^{(d)}) \] indicating the probability that \( x \) is a real training example rather than a fake sample drawn from the model
GAN Architecture

$G$ and $D$ are deep neural networks
Fine tune training consists of backpropagation
Interaction between $G$ and $D$

- Weights are updated so as to
  - maximize the probability that any real data input $x$ is classified as belonging to the real dataset, while
  - minimizing the probability that any fake image is classified as belonging to the real dataset

- In more technical terms,
  - Loss function maximizes the function $D(x)$, and it also minimizes $D(G(z))$
Value function

- Value Function of Minimax Game played by Generator and Discriminator

\[
\min_G \max_D V(D, G) = \mathbb{E}_{x \sim p_{\text{data}}(x)}[\log D(x)] + \mathbb{E}_{z \sim p_z(z)}[\log(1 - D(G(z)))]
\]
Algorithm 1 Minibatch stochastic gradient descent training of generative adversarial nets. The number of steps to apply to the discriminator, $k$, is a hyperparameter. We used $k = 1$, the least expensive option, in our experiments.

for number of training iterations do
    for $k$ steps do
        • Sample minibatch of $m$ noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_g(z)$.
        • Sample minibatch of $m$ examples $\{x^{(1)}, \ldots, x^{(m)}\}$ from data generating distribution $p_{\text{data}}(x)$.
        • Update the discriminator by ascending its stochastic gradient:
          \[
          \nabla_{\theta_d} \frac{1}{m} \sum_{i=1}^{m} \left[ \log D\left(x^{(i)}\right) + \log \left(1 - D\left(G\left(z^{(i)}\right)\right)\right) \right].
          \n          \]
    end for
    • Sample minibatch of $m$ noise samples $\{z^{(1)}, \ldots, z^{(m)}\}$ from noise prior $p_g(z)$.
    • Update the generator by descending its stochastic gradient:
      \[
      \nabla_{\theta_g} \frac{1}{m} \sum_{i=1}^{m} \log \left(1 - D\left(G\left(z^{(i)}\right)\right)\right).\]
end for

The gradient-based updates can use any standard gradient-based learning rule. We used momentum in our experiments.
