Topics in Optimization for Deep Models

• Importance of Optimization in machine learning
• How learning differs from optimization
• Challenges in neural network optimization
• Basic Optimization Algorithms
• Parameter initialization strategies
• Algorithms with adaptive learning rates
• Approximate second-order methods
• Optimization strategies and meta-algorithms
Topics in Second Order Methods

1. Overview
2. Newton’s Method
3. Conjugate Gradients
   – Nonlinear Conjugate Gradients
4. BFGS
   – Limited Memory BFGS
Why second-order methods?

- Better direction

- Better step-size
  - A full step jumps directly to the minimum of the local squared approx.
  - Often this is already a good heuristic
  - Additional step size reduction and dampening are straightforward
Overview

• We discuss here second order methods of training deep networks

• The only objective function examined is empirical risk:
  – Empirical risk, with $m$ training examples, is

$$J(\theta) = E_{(x,y) \sim \hat{p}_{data}} \left( L(f(x;\theta), y) \right) = \frac{1}{m} \sum_{i=1}^{m} L(f(x^{(i)};\theta), y^{(i)})$$

  $f(x; \theta)$ is the predicted output when the input is $x$
  $y$ is target output
  $L$ is the per-example loss function

  – Methods extend readily to other objective functions such as those that include parameter regularization
Newton’s Method

• In contrast to first order gradient methods, second order methods make use of second derivatives to improve optimization
• Most widely used second order method is Newton’s method
• It is described in more detail here emphasizing neural network training
• It is based on Taylor’s series expansion to approximate $J(\theta)$ near some point $\theta_0$ ignoring derivatives of higher order
Newton Update Rule

- Taylor’s series to approximate $J(\theta)$ near $\theta_0$

\[
J(\theta) \approx J(\theta_0) + (\theta - \theta_0)^T \nabla_{\theta} J(\theta_0) + \frac{1}{2} (\theta - \theta_0)^T H(\theta - \theta_0)
\]

- where $H$ is the Hessian of $J$ wrt $\theta$ evaluated at $\theta_0$

- Solving for the critical point of this function we obtain the Newton parameter update rule

\[
\theta^* = \theta_0 - H^{-1} \nabla_{\theta} J(\theta_0)
\]

- Thus for a quadratic function (with positive definite $H$) by rescaling the gradient by $H^{-1}$ Newton’s method directly jumps to the minimum

- If objective function is convex but not quadratic (there are higher-order terms) this update can be iterated yielding the training algorithm given next
Training Algorithm associated with Newton’s Method

Algorithm: Newton’s method with objective:

\[
J(\theta) = \frac{1}{m} \sum_{i=1}^{m} L(f(x^{(i)}; \theta), y^{(i)})
\]

Require: Initial parameter \( \theta_0 \)
Require: Training set of \( m \) examples

while stopping criterion not met do
  Compute gradient: \( g \leftarrow \frac{1}{m} \nabla_{\theta} \sum_{i} L(f(x^{(i)}; \theta), y^{(i)}) \)
  Compute Hessian: \( H \leftarrow \frac{1}{m} \nabla^2_{\theta} \sum_{i} L(f(x^{(i)}; \theta), y^{(i)}) \)
  Compute Hessian inverse: \( H^{-1} \)
  Compute update: \( \Delta \theta = -H^{-1}g \)
  Apply update: \( \theta = \theta + \Delta \theta \)
end while
Positive Definite Hessian

- For surfaces that are not quadratic, as long as the Hessian remains positive definite, Newton’s method can be applied iteratively.
- This implies a two-step procedure:
  - First update or compute the inverse Hessian (by updating the quadratic approximation).
  - Second, update the parameters according to

\[
\theta^* = \theta_0 - H^{-1}\nabla_0 J(\theta_0)
\]
Regularizing the Hessian

- Newton’s method is appropriate only when the Hessian is positive definite
  - In deep learning the surface of the objective function is nonconvex
    - Many saddle points: problematic for Newton’s method
- Can be avoided by regularizing the Hessian
  - Adding a constant $\alpha$ along the Hessian diagonal

$$\theta^* = \theta_0 - \left[H(f(\theta_0)) + \alpha I\right]^{-1} \nabla_\theta f(\theta_0)$$
Motivating Conjugate Gradients

• Method to efficiently avoid calculating $H^{-1}$
  – By iteratively descending conjugate directions

• Arises from steepest descent for quadratic bowl has an ineffective zig-zag pattern
  – Since each line direction is orthogonal to previous
    • Let previous search direction be $d_t$
    • Then $\nabla_{\theta} J(\theta) d_{t-1} = 0$
    • Current search direction will have no contribution in direction $d_{t-1}$
    • Thus $d_t$ is orthogonal to $d_{t-1}$
    • Method of conjugate gradients addresses this problem
Imposing Conjugate Directions

- We seek to find a search direction that is conjugate to the previous line search direction.
- At iteration $t$ the next search direction $d_t$ takes the form $d_t = \nabla_\theta J(\theta) + \beta_t d_{t-1}$
- Directions $d_t$ and $d_{t-1}$ are conjugate if $d_t^T Hd_{t-1} = 0$
- Methods for imposing conjugacy
  - Fletcher-Reeves
    $$\beta_t = \frac{\nabla_\theta J(\theta_t)^T \nabla_\theta J(\theta_t)}{\nabla_\theta J(\theta_{t-1})^T \nabla_\theta J(\theta_{t-1})}$$
  - Polak-Ribiere
    $$\beta_t = \frac{(\nabla_\theta J(\theta_t) - \nabla_\theta J(\theta_{t-1}))^T \nabla_\theta J(\theta_t)}{\nabla_\theta J(\theta_{t-1})^T \nabla_\theta J(\theta_{t-1})}$$
Conjugate gradient algorithm

Algorithm The conjugate gradient method

Require: Initial parameters $\theta_0$
Require: Training set of $m$ examples
  - Initialize $\rho_0 = 0$
  - Initialize $g_0 = 0$
  - Initialize $t = 1$
while stopping criterion not met do
  Initialize the gradient $g_t = 0$
  Compute gradient: $g_t \leftarrow \frac{1}{m} \nabla_{\theta} \sum_i L(f(x^{(i)}; \theta), y^{(i)})$
  Compute $\beta_t = \frac{(g_t - g_{t-1})^T g_t}{g_{t-1}^T g_{t-1}}$ (Polak-Ribièrè)
  (Nonlinear conjugate gradient: optionally reset $\beta_t$ to zero, for example if $t$ is a multiple of some constant $k$, such as $k = 5$)
  Compute search direction: $\rho_t = -g_t + \beta_t \rho_{t-1}$
  Perform line search to find: $\epsilon^* = \arg\min_{\epsilon} \frac{1}{m} \sum_{i=1}^{m} L(f(x^{(i)}; \theta_t + \epsilon\rho_t), y^{(i)})$
  (On a truly quadratic cost function, analytically solve for $\epsilon^*$ rather than explicitly searching for it)
  Apply update: $\theta_{t+1} = \theta_t + \epsilon^* \rho_t$
  $t \leftarrow t + 1$
end while
The BFGS Algorithm

- **Broyden-Fletcher-Goldfarb-Shanno (BFGS)**
  - Newton’s method without the computational burden
  - It is similar to the conjugate gradient method
    - More direct approach to approximating Newton’s update

- **Recall Newton’s update:**
  \[
  \theta^* = \theta_0 - H^{-1}\nabla_{\theta} J(\theta_0)
  \]
  - where \( H \) is the Hessian of \( J \) wrt \( \theta \) evaluated at \( \theta_0 \)
  - Primary difficulty is computation of \( H^{-1} \)
  - BFGS is quasi Newton: approximates \( H^{-1} \) by matrix \( M_t \) that is iteratively refined by low-rank updates
    - Once the inverse Hessian \( M_t \) is updated, the direction of descent \( \rho_t \) is determined by \( \rho_t = M_t g_t \)
    - Final update to parameters is \( \theta_{t+1} = \theta_t + \epsilon^* \rho_t \)
