

# New Paradigms in Pattern Recognition

Sargur N. Srihari

[srihari@cedar.buffalo.edu](mailto:srihari@cedar.buffalo.edu)

# Outline

- Pattern Recognition and Machine Learning
- Generative and Discriminative Classifiers
  - Conditional Random Fields
- Document Recognition Applications
- Summary and Conclusion

# Pattern Recognition

- Searching for Patterns in data is a fundamental one with a long and successful history
  - 16<sup>th</sup> cent:  
Empirical observations of Tycho Brahe allowed Johannes Kepler to discover empirical laws of planetary motion which in turn provided springboard for classical mechanics
  - Early 20<sup>th</sup> cent:  
Discovery of regularities in atomic spectra played key role in development and verification of quantum mechanics

# Machine Learning

- Programming computers to use example data or past experience
- Well-Posed Learning Problems
  - A computer program is said to learn from *experience*  $E$
  - with respect to *class of tasks*  $T$  and *performance measure*  $P$ ,
  - if its performance at tasks  $T$ , as measured by  $P$ , improves with experience  $E$ .

# Pattern Recognition and Machine Learning

- Two facets of the same field
- Pattern Recognition origins are in engineering
  - discovering regularities in data and taking actions such as classification
- Machine Learning grew out of computer science
  - Needed in cases where we cannot directly write a computer program but have example data

# Example Problem: Handwritten Digit Recognition

Wide variability of same numeral

- Handcrafted rules will result in large no of rules and exceptions
- Better to have a machine that learns from a large training set

# Meeting of the MINDS

- Machine Learning
- Information Retrieval
- Natural Language Processing
- Document Analysis and Recognition
- Speech Recognition

# ML in NLP: Text Categorization Problem

**Task  $T$ :**

Assign a document to its content category

**Performance measure  $P$ :**

Precision and Recall

**Training experience  $E$ :**

Example pre-classified documents

# ML in Speech and IR

- **Speech Recognition**
  - Speaker-specific strategies for recognizing phonemes and words
  - Neural networks and methods for learning HMMs for customizing to individual speakers, vocabularies and microphone characteristics
- **Information Retrieval and Data Mining**
  - Information extraction from text
  - Very large databases to learn general regularities in data

# Major Developments in PR-ML in Last 10 years

- Bayesian methods
  - From niche to main stream
  - Approximate inference using variational methods
- Graphical models
  - Emerged as general framework for describing and applying probabilistic models
- Models based on kernels have had significant impact
  - SVM
- Distance-based methods

# PR-ML Methods

- Generative Methods
  - Model class-conditional pdfs and prior probabilities
  - Known as generative since by sampling them can generate synthetic data points
- Discriminative Methods
  - Directly estimate the posterior probabilities

# Generative Models

- System's input features, output response and latent variables are represented by joint pdfs
- Popular models:
  - Gaussians, Naïve Bayes, Mixtures of multinomials
  - Mixtures of Gaussians, Mixtures of experts, HMMs
  - Sigmoidal belief networks, Bayesian networks
  - Markov random fields
- Prior knowledge is added parametrically

# Generative Learning

- Given a problem domain with variables  $X_1, \dots, X_T$  system is specified with a joint pdf  $P(X_1, \dots, X_T)$
- Given a full joint pdf we can
  - Marginalize 
$$P(X_j) = \sum_{\forall X_i, i \neq j} P(X_1, \dots, X_n)$$
  - Condition 
$$P(X_j | X_k) = \frac{P(X_j, X_k)}{P(X_k)}$$
- By conditioning a joint pdf we can easily form
  - Classifiers, regressors, predictors

# Constraining joint distribution

- To have fewer degrees of freedom
  - Conditional independencies between variables

Bayesian Network

$$P(X_1, \dots, X_n) = \prod_{i=1}^n P(X_i | X_{\Pi_i})$$

Graph shows that joint distribution factorizes over variables given their parents

# Generative Models (graphical)

(a) Mixture Model

Parent node  
selects between  
components

### (b) Directed Graphical Model

## 3) Undirected Graphical Model

Parent node  
selects between  
components

# Quick Medical Reference -DT

## Diagnosing Diseases from Symptoms

# Markov Random Field

# Generative Hidden Markov Model

HMM is a distribution depicted by a graphical model.  
Highly structured network indicates conditional independences,  
Past states independent of future states  
Conditional independence of observed given its state

# Successes of Generative Methods

- NLP
  - Traditional rule-based or Boolean logic systems (eg Dialog and Lexis-Nexis) are giving way to statistical approaches (Markov models and stochastic context free grammars)
- Medical Diagnosis
  - QMR knowledge base, initially a heuristic expert systems for reasoning about diseases and symptoms has been augmented with decision theoretic formulation
- Genomics and Bioinformatics
  - Sequences represented as generative HMMs

# Discriminative Classifiers

- Make no attempt to model underlying distributions
- Only interested in optimizing a mapping from inputs to desired outputs
- Focuses model and computational resources on given task and provides better performance
- Examples:
  - logistic regression
  - SVMs
  - traditional neural networks
  - Nearest neighbor

$$P(y=1 | X) = \frac{1}{(1 + \exp(-\theta^T X))}$$

sigmoid

# Discriminative Classifier: SVM

(a) Support Vector Machine

(b) Mapped Data

(c) Separating Hyperplane

$$(x_1, x_2) \rightarrow (x_1, x_2, x_1 x_2)$$

Nonlinear decision boundary

Linear boundary

# SVM Nonlinear Case

$$\varphi(x) = (1, x, x^2)^t$$

- First choose the non-linear phi functions
  - To map input vector to a higher dimensional feature space
- Dimensionality of space can be arbitrarily high only limited by computational resources
- Each pattern  $x_k$  transformed into pattern  $y_k$  where

$$\mathbf{y}_k = \Phi(\mathbf{x}_k)$$

# Support Vectors

- Support vectors are nearest patterns at distance  $b$  from hyperplane
- $b$  = maximum distance from nearest training patterns

Three support vectors are shown as solid dots

# Discriminative Classifier applications

- Image and document classification
- Biosequence analysis
- Time series prediction

# Disadvantages of Discriminative Classifiers

- Lack elegance of generative
  - Priors, structure, uncertainty
- Alternative notions of penalty functions, regularization, kernel functions
- Feel like black-boxes
  - Relationships between variables are not explicit and visualizable

# Bridging Generative and Discriminative

- Can performance of SVMs be combined elegantly with flexible Bayesian statistics?
- Maximum Entropy Discrimination marries both methods
  - Solve over a distribution of parameters (a distribution over solutions)

# Conditional Random Fields

A CRF is the conditional distribution  $p(Y|X)$  with the graphical structure:

**X** is the observed data sequence which is to be labeled  
**Y** is the random variable over the label sequences

# Graphical structures of HMMs, MEMMs and CRFs

Hidden Markov  
Model(HMM)

Max Entropy  
Markov Model  
(MEMM)

Conditional  
Random  
Field(CRF)

# Advantage over Generative models

- CRF models conditional probability  $P(\text{label } Y \mid \text{observed } X)$  as compared to generative models like HMM which model joint probability  $P(Y, X)$
- Relaxes assumption of conditional independence of observed data given the labels
- It can contain a number of arbitrary feature functions
- Each feature function can use entire input data sequence. Probability of label at observed data segment may depend on any past or future data segments.

# Advantage over other Discriminative Models

- CRF avoids limitation of MEMMs and other discriminative Markov models which can be biased towards states with few successor states.
- CRF has a single exponential model for joint probability of entire sequence of labels given the observation sequence.
- In MEMMs,  $P(y | x) = \text{product of factors}$ , one for each label. Each factor depends only on previous label, and not future labels

# Applications in Document Analysis

- CRFs can be used in sequence labeling tasks
- Zone Labeling –
  - Signature Extraction, Noise Removal
- Pixel Labeling –
  - Binarization of documents
- Character level labeling
  - Recognition of Handwritten Words

# Applications

- Recognition of Handwritten Words
- Labeling scanned documents
- Binarization of documents
- Document Image Retrieval

# Document Image Retrieval

- Signature Extraction

Original Document

Extracted Signature

- Signature Retrieval

# Signature Extraction

A Patch is defined to be a group of connected components

# Segmentation into Patches

- Patches generated using region growing algorithm
- Size of patch optimized to represent size of word
- Region within each rectangle represents a patch

# Neighboring Patch Detection

- Six neighbors are identified for each patch
- Closest(top/bottom) and two closest(left/right) in between patches are considered neighbors.

# CRF for Zone Labeling

The probabilistic model of the Conditional Random Field used is

$$P(\mathbf{y}|\mathbf{x}, \theta) = \frac{e^{\psi(\mathbf{y}, \mathbf{x}; \theta)}}{\sum_{\mathbf{y}'} e^{\psi(\mathbf{y}', \mathbf{x}; \theta)}} \quad \begin{aligned} \text{where } \mathbf{y}_i &\in \{\text{Machine-print, Handwriting, Noise}\} \\ \theta &: \text{CRF model parameters} \\ \mathbf{x} &: \text{Observed document} \end{aligned}$$

$$\psi(\mathbf{y}, \mathbf{x}; \theta) = \sum_{j=1}^m \left( A(j, y_j, \mathbf{x}; \theta^s) + \sum_{(j,k) \in E} I(j, k, y_j, y_k, \mathbf{x}; \theta^t) \right)$$

where  $A(j, y_j, \mathbf{x}; \theta^s)$  : association potential

it associates the characteristics of that patch with its corresponding label

$I(j, k, y_j, y_k, \mathbf{x}; \theta^t)$  : interaction potential

it captures the neighbor/contextual dependencies by associating pair wise interaction of the neighboring labels and the observed data

$m$  : non-overlapping patches

# CRF Parameter Estimation and Inference

- Parameter estimation
  - Done by maximizing pseudo-likelihood parameters using conjugate gradient descent with line search optimization
- Inference
  - Labels are assigned to each patch using Gibbs Sampling
  - Initially random labels are assigned to each patch
  - Over several iterations the label for each patch is generated from a distribution conditioned on the current values of its neighbors.

$$\hat{\theta}_{ML} \approx \arg \max_{\theta} \prod_{i=1}^M P(y_i | y_{\mathcal{N}_i}, \mathbf{x}, \theta)$$

# Features for HW/Print/Noise Classification

State Feature	Description
Height	Maximum height of the patch
Avg component width	The mean width of the connected components within a patch
Density	Density of foreground pixels within the patch
Aspect ratio	Width/Height of the patch
Gabor filter	8 features capturing the different stroke orientations
Variation of height	Variation in height within a patch
Width variation	Variation in width within a patch
Overlap	Sum of overlap in area between the connected components within a patch
Percentage of text above	Relative location of the patch with respect to the entire document
Number of components	Count of the connected components within a patch
Maximum component size	Maximum size of a component within a patch
Points in convex hull	Number of points in the convex hull of the patch
Maximum run length	The maximum horizontal run length within a patch
Avg run length	The average horizontal run length within a patch
Horizontal Transitions	A count of the number of times the pixel value transitions from white to black horizontally
Vertical Transitions	A count of the number of times the pixel value transitions from white to black vertically

Transition Feature	Description
Relative location	Assigned weights based on the relative location - top/bottom or right/left
Convex hull distance	The convex hull distance between the 2 patches
Ratio of aspect ratio	The ratio of the aspect ratio values of the 2 patches
Ratio of number of components	The ratio of the number of components present in the 2 patches

# Precision-Recall Curves for signature retrieval results

Precision of 84.2% at Recall of 78.4% after Query Expansion

# Word Recognition Objective

- To transform the Image of a Handwritten Word to text using a pre-specified lexicon
  - Accuracy depends on lexicon size

The image shows a line of handwritten text in black ink: "We were referred to you". Overlaid on this text are several colored annotations: "We" is in green with a small red "We" above it; "were" is in red with a small red "were" below it; "referred" is in blue with a small red "referred" below it; "to" is in orange with a small orange "to" above it; and "you" is in purple with a small red "you" below it.

# Graphical Model of CRF for Word Recognition

# Segmentation Based Word Recognition

- Word image is divided into several segmentation points.
- Dynamic programming used to find best grouping of segments into characters

$$P(\mathbf{y}|\mathbf{x}, \theta) = \max_i (P(\mathbf{y}|\mathbf{x}, s_i) P(s_i))$$

$\mathbf{y}$  is the text of the word,  $\mathbf{x}$  is observed handwritten word,  $\mathbf{s}$  is a grouping of segmentation points

# CRF Model

Probability of recognizing a handwritten word image,  $\mathbf{X}$  as the word ‘the’ is given by

$$P(\mathbf{y} = 'the' | \mathbf{x}, \theta) = \frac{e^{\psi(y = 't', x; \theta)}}{\sum_{y' = 'a'}^{z'} e^{\psi(y', x; \theta)}} \frac{e^{\psi(y = 'h', y_n = 't', x; \theta)}}{\sum_{y' = 'a'}^{z'} e^{\psi(y', y_n = 't', x; \theta)}} \frac{e^{\psi(y = 'e', y_n = 'h', x; \theta)}}{\sum_{y' = 'a'}^{z'} e^{\psi(y', y_n = 'h', x; \theta)}}$$

$$\psi(y, y_n | \mathbf{x}; \theta) = A(j, y, \mathbf{x}; \theta^s) + I(j, k, y, y_n, \mathbf{x}; \theta^t)$$

Captures the state features for a character

Captures the transition features between a character and its preceding character in the word

# Word Features

- State features include
  - 74 WMR features
  - Distance between observed character segment and a codebook of characters
  - Height, width, aspect ratio, position in the text, etc
- Transition features include
  - Vertical overlap
  - Total width of the bigram
  - Difference in the height, width, aspect ratio, etc

# Word Recognition: WMR features

2 Global Features: Aspect ratio  
Stroke ratio

72 Local Features

$$F(i,j) = \frac{s(i,j)}{N(i)*S(j)} \quad i = 1, 9 \quad j = 0, 7$$

$s(i,j)$  - no. of components with slope  $j$  in sub image  $i$

$N(i)$  - no. of components in sub image  $i$

$$S(j) = \max \frac{s(i,j)}{N(i)}$$

# Automatic Word Recognition

# Summary

- Pattern Recognition and Machine Learning techniques are facets of same problem
- Many advances in past decade
- Play central role in IR, NLP, DAR, SR
- Classification algorithms are either generative or discriminative
  - former involve modeling, latter directly solve classification
- CRFs are a natural choice for several labeling tasks
  - Main disadvantage is cost of training
  - Good performance on labeling tasks in DAR
